ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

# Foreword

The original RADC (now Rome Laboratory) Reliability Engineer's Toolkit, July 1988, proved to be a best seller among military, industry and academic reliability practitioners. Over 10,000 copies were distributed and the Toolkit and its authors received the 1989 Federal Laboratory Consortium Special Award for Excellence in Technology Transfer.

This updated version, completed in-house at the Systems Reliability Division, contains new topics on accelerated testing, thermal analysis, surface mount technology, design of experiments, hardware/software reliability, component failure modes/mechanisms, dormancy, and sneak analysis. Revisions and updates in most other areas were also made.

This revision was led by a project team consisting of Bruce Dudley, Seymour Morris, Dan Richard and myself. We acknowledge the fine support we received from technical contributors Frank Born, Tim Donovan, Barry McKinney, George Lyne, Bill Bocchi, Gretchen Bivens, Doug Holzhauer, Ed DePalma, Joe Caroli, Rich Hyle, Tom Fennell, Duane Gilmour, Joyce Jecen, Jim Ryan, Dr. Roy Stratton, Dr. Warren Debany, Dan Fayette, and Chuck Messenger. We also thank typists Elaine Baker and Wendy Stoquert and the Reliability Analysis Center's MacIntosh Whiz, Jeanne Crowell.

Your comments are always welcome. If you wish to throw bouquets, these people should receive them. If it's bricks you're heaving, aim them at Bruce, Seymour, or me at the address below.

Anthony J. Feduccia Rome Laboratory/ERS 525 Brooks Road Griffiss AFB, NY 13441-4505

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

#### Introduction

#### Purpose

This Toolkit is intended for use by a practicing reliability and maintainability (R&M) engineer. Emphasis is placed on his or her role in the various R&M activities of an electronic systems development program. The Toolkit is not intended to be a complete tutorial or technical treatment of the R&M discipline but rather a compendium of useful R&M reference information to be used in everyday practice.

#### Format

The format of the Toolkit has been designed for easy reference. Five main sections are laid out to follow the normal time sequence of a military development program.

Descriptions of the "how to" of the R&M engineer's activities have been designed to take the form of figures, tables, and step-by-step procedures as opposed to paragraphs of text. Appendices are included to give a greater depth of technical coverage to some of the topics as well as to present additional useful reference information.

The Toolkit also includes a "Quick Reference Application Index" which can be used to quickly refer the R&M engineer to the portion of a section that answers specific questions. A quick reference "For More Help Appendices" index is also included for the more in-depth topics of the appendices.

Ordering information for the military documents and reports listed in the Toolkit is located in Appendix 10.

#### Terminology

The term "Reliability" used in the title of this document is used in the broad sense to include the field of maintainability. The content of the report addresses reliability and maintainability (R&M) because they are usually the responsibility of one government individual in a military electronics development program. In this context, testability is considered as a part of maintainability and is, therefore, inherently part of the "M" of "R&M." Where testability issues, such as development of quantitative requirements, are appropriate for separation from "M" discussion, they are and have been labeled accordingly.

#### **Underlying Philosophy**

The development and application of a successful reliability program requires a number of tasks and coordination steps. Key ingredients include:

- Aggressive Program Manager Support
- Firm and Realistic Requirements
- Effective Built-in-Test
- Failure Reporting & Corrective Action

#### **Total Quality Management**

- Thorough Technical Reviews
- Complete Verification
- Parts Control

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

1

Total Quality Management (TQM) is an approach which puts quality first as the means to long-term survival and growth. It employs teamwork to improve the processes used by an organization in providing products and services. One could argue that TQM encompasses Reliability Engineering or that Reliability Engineering encompasses many TQM activities. Either way, the reliability engineer may well get involved in TQM. For example, he/she may be asked to evaluate a contractor's TQM approach, assist process improvement teams with statistical analyses, or serve as a member of a process improvement team looking at his/her own agency's processes. It, therefore, behooves the reliability professional to have some knowledge of TQM.

#### Principles of TQM

- **Management Leadership:** For successful TQM, the company management must create a cultural change from authoritarian management focused on short-term goals to using the full potential of all employees for long-term benefit. This means the agency executives must be consistent, persistent and personally involved in the pursuit of quality.
- Focus on Customer: It is easy to appreciate the need to focus on the external customer. Less obvious is the concept of internal customer satisfaction. Reliability engineering, for example, may be asked by Design Engineering (the customer) to review a proposed design for reliability. If an incomplete or shoddy evaluation is done, the ultimate design may not meet specifications. Output suffers and so does the efficiency of the project team. A TQM oriented organization seeks to understand and delight its customers, both external and internal.
- **Constant Improvement:** It is estimated that about 25% of operating costs of a typical manufacturing agency go for rework and scrap. Service organizations pay an even higher penalty for not doing things right the first time. Reducing these costs is a potential source of vast profit. Hence, TQM agencies seek to constantly improve their processes. The usual change agent is a team with members from all offices involved in the process, and including those who actually perform the work. Besides the measurable benefits, process improvements mean fewer defects going to customers, with an unmeasurable but significant effect on the bottom line.
- Use of Measurements and Data: TQM agencies seek to measure quality so that improvements can be tracked. Every process will have some operational definition of quality. The overall agency progress can be measured by calculating the "cost of quality" (money spent for preventing defects, appraising quality, rework and scrap). Typically, as more money is spent on preventing defects, savings made in scrap and rework reduce the overall cost of quality. Another common approach is to score the agency using the criteria for the Malcolm Baldrige National Quality Award as a measure. For Government agencies, the scoring criteria for the Office of Management and Budget (OMB) Quality Improvement Prototype Award is used in lieu of the Malcolm Baldrige criteria. R&M engineers should use Statistical Process Control, Statistical Design of Experiments, Quality Function Deployment, Taguchi Methods, and other available quality tools.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

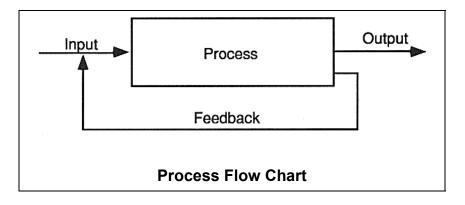

Design of Experiments is explained in Topic T14. Statistical Process Control techniques are described in this topic.

- Employee Involvement: A TQM agency recognizes the value of a skilled work force cooperating to satisfy the customer. Extensive education and training programs exist. Training in job skills, quality methods, and team building techniques is widely available. Cooperation between offices is the norm (e.g. concurrent engineering). Employees on all levels are widely involved in process improvement teams. Management looks for ways of reducing the hassle created by bureaucratic rules and regulations. Employees are trusted and empowered to do their jobs.
- **Results:** In a TQM agency, improvement is continuous and measured. Image building measurements like the number of improvement teams formed, are of less value than measures of cost of quality or increase in production which show real results. Management is not concerned with filling squares, but with making worthwhile changes.

#### **TQM** Tools

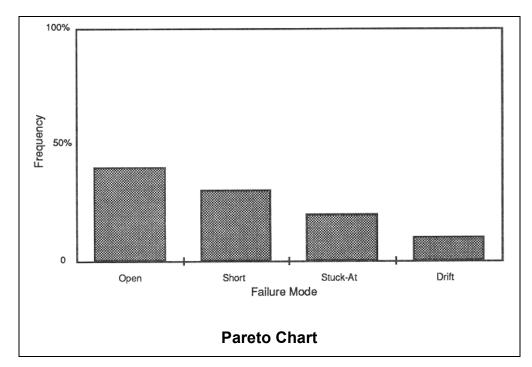

• **Process Flow Chart:** A diagram showing all the major steps of a process. The diagram also shows how the various steps in the process relate to each other.

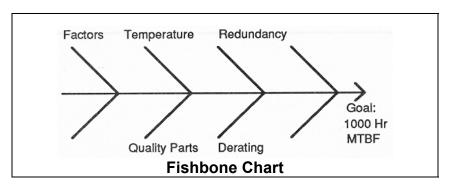

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

• **Pareto Chart:** A bar graph of identified causes shown in descending order of frequency used to prioritize problems and/or data. The Pareto Principle states that a few causes typically account for most problems (20% of the serial numbered units account for 80% of the failures; 20% of the people do 80% of the work; etc.) Pareto diagrams help analyze operational data and determine modes of failure. They are especially useful when plotted before and after an improvement project or redesign to show what progress has been made.

• **Fishbone Chart:** A cause and effect diagram for analyzing problems and the factors that contribute to them, or, for analyzing the factors that result in a desired goal. Also called an Ishikawa Chart. This tool requires the listing of all possible factors contributing to a result and the subsequent detailed investigation of each factor. It is usually developed in brainstorming sessions with those that are familiar with the process in question.

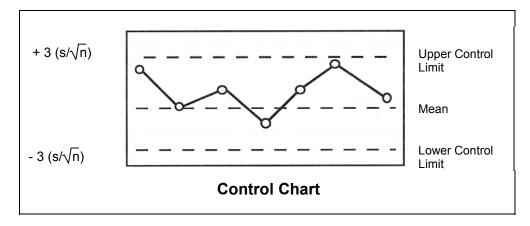

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

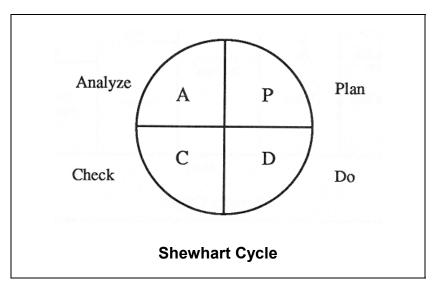

4

• **Control Chart:** A method of monitoring the output of a process or system through the sample measurement of a selected characteristic and the analysis of its performance over time. There are two main types: control charts for attributes (to plot percentages of "go/no go" attribute data) and control charts for variables (to plot measurements of a variable characteristic such as size or weight). Control charts identify changes in a process as indicated by drift, a shift in the average value, or, increased variability. The upper and lower control limits are based on the sample mean (x), sample standard deviation (s) and the sample size (n).

• **Shewhart Cycle:** A method, created by Walter A. Shewhart, for attacking problems.

The cycle starts with the planning phase: defining the particular problem, deciding what data are needed and determining how to obtain the data; that is via test, previous history, external sources, etc. The process flow charts and Ishikawa diagrams are very useful at this point.

After planning it is necessary to do something (D on the chart); Getting the data needed, running a test, making a change, or, whatever the plan calls for.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

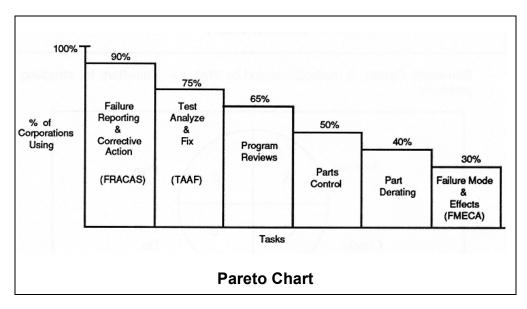

The next step, C on the chart, is to check the results. In some instances, this would be done by a control chart. In any event the results are evaluated and causes of variation investigated. Histograms, Pareto Charts and Scattergrams can be helpful.

The last step, A, stands for Analyze and Act. What did the data in step C indicate? Based on the analysis, appropriate action is taken. This could be a process change or a decision that a new plan is needed. In any event, after you act, you go back to P and start another cycle. Even if the first trip around worked wonders, there are always more opportunities waiting to be discovered. The cycle is really a spiral going upward to better and better quality.

#### Reliability TQM Tasks

Many corporations have considered or utilized TQM principles. The reliability tasks most frequently used in producing a quality product are assembled in the following Pareto chart:

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

#### Department of Defense R&M Policy and Procedures

Department of Defense (DoD) Directive 5000.1, Defense Acquisition (23 Feb 91), establishes management policies and procedures for acquiring systems which satisfy all aspects of user operational needs. It is based on the principles contained in the Defense Management Report to the President (prepared by the Secretary of Defense, Jul 89). DoD Directive 5000.1 cancels 63 other DoD directives and policy memorandum, and replaces them with a single reference; DoD Instruction 5000.2, Defense Acquisition Policies and Procedures (23 Feb 91). The following R&M related documents are included in these cancellations: (1) DoD Instruction 3235.1, "Test and Evaluation of System Reliability, Availability and Maintainability", 1 Feb 82, (2) DoD Instruction 4120.19, "DoD Parts Control Program", 6 Jul 89. and (3) DoD Directive 5000.40, "Reliability and Maintainability", 8 Jul 80.

DoD Instruction 5000.2 establishes an integrated framework for translating broadly stated mission needs into an affordable acquisition program that meets those needs. It defines an event oriented management process that emphasizes acquisition planning, understanding of user needs and risk management. It is several hundred pages long and has 16 separate parts covering everything from Requirements Evolution and Affordability to the Defense Acquisition Board Process. Part 6, Engineering and Manufacturing, Subsection C, Reliability and Maintainability, establishes DoD R&M policy. The basic R&M policies and procedures described in this seven page section can be summarized as follows:

#### Policies

- Understand user needs and requirements.
- Actively manage all contributors to system unreliability.
- Prevent design deficiencies and the use of unsuitable parts.
- Develop robust systems insensitive to use environments.

#### Procedures

- Define both mission and logistics R&M objectives based on operational requirements and translate them into quantitative contractual requirements.
- Perform R&M allocations, predictions, and design analysis as part of an iterative process to continually improve the design.
- Establish parts selection and component derating guidelines.
- Preserve reliability during manufacturing through an aggressive environmental stress screening program.
- Establish a failure reporting and corrective action system.
- Perform reliability growth and demonstration testing.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

7

 Use MIL-STD-785 (Reliability Program for Systems & Equipment, Development and Production) and MIL-STD-470 (Maintainability Program for Systems & Equipment) for R&M program guidance.

This Toolkit, although not structured to address each policy and procedure per se, addresses the practical application of the procedures to the development of military electronic hardware.

#### Insight

Requirement development is critical to program success. Military standards (MIL-STDs) cannot be blindly applied. Requirements must be tailored to the individual program situation considering the following:

- Mission Criticality
- Operational Environment
- Phase of Development
- Other Contract Provisions (incentives, warranties, etc.)
- Off-The-Shelf Versus Newly Designed Hardware

#### **Topic R1: Quantitative Reliability Requirements**

#### **Scope of Requirements**

Reliability parameters expressed by operational users and ones specified in contractual documents take many forms. Tables R1-1 and R1-2 identify the characteristics of reliability parameters.

### Table R1-1: Logistics (Basic) and Mission Reliability Characteristics

Logistics (Basic) Reliability	Mission Reliability
<ul> <li>Measure of system's ability to operate without logistics support</li> </ul>	Measure of system's ability to complete mission
<ul> <li>Recognize effects of all occurrences that demand support without regard to effect on mission</li> </ul>	Consider only failures that cause mission abort
Degraded by redundancy	Improved by redundancy
Usually equal to or lower than mission reliability	Usually higher than logistics reliability

## Table R1-2: Operational and Contractual Reliability Characteristics

Contractual Reliability		Operational Reliability	
	Jsed to define, measure and evaluate contractor's program	<ul> <li>Used to describe reliability performance when operated in planned environment</li> </ul>	
• [	Derived from operational needs		
	Colocted such that achieving them	<ul> <li>Not used for contract reliability requirements (requires</li> </ul>	!
a	Selected such that achieving them allows projected satisfaction of operational reliability	translation)	
• E	Expressed in inherent values	Used to describe needed level of reliability performance	
	Account only for failure events subject to contractor control	<ul> <li>Include combined effects of item design, quality, installation environment,</li> </ul>	
	nclude only design and nanufacturing characteristics	maintenance policy, repair, etc.	

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

Contractual Reliability	Operational Reliability
Typical terms	<ul> <li>Typical terms</li> </ul>
- MTBF(mean-time-between-failures)	<ul> <li>MTBM (mean-time-between- maintenance)</li> </ul>
<ul> <li>Mission MTBF (sometimes also</li> </ul>	
called MTBCF)	<ul> <li>MTBD (mean-time-between- demand)</li> </ul>
	<ul> <li>MTBR (mean-time-between- removal)</li> </ul>
	- MTBCF (mean-time-between- critical-failure)

#### **Operational Constraints**

- Mission Criticality
- Availability Constraints
- Self-Sufficiency Constraints
- Attended/Unattended Operation
- Operational Environment
- Use of Off-the-shelf or Newly Designed Equipment

#### How to Develop Requirements

Figure R1-1 defines the general reliability requirement development process. Key points to recognize from this process are:

 User requirements can be expressed in a variety of forms that include combinations of mission and logistics reliability, or they may combine reliability with maintainability in the form of availability. Conversion to commonly used operational terms such as mean-time-between-maintenance (MTBM) and mean-time-between-critical-failure (MTBCF) must be made from terms such as operational availability (A<sub>0</sub>) and break-rate, etc., to enable translation to parameters which can be specified in contracts.

An example is:

 $A_0 = \frac{MTBM}{MTBM + MDT}$ 

(Solve for MTBM using mean downtime (MDT) which includes the actual repair time plus logistics delay time.)

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

12

- 2. Since operational reliability measures take into account factors beyond the control of development contractors, they must be translated to contractual reliability terms for which contractors can be held accountable. (Appendix 1 provides one means of accomplishing this translation.)
- 3. The process cannot end with the translation to a contractual value. Evaluation of the realism of the translated requirements is a necessary step. Questions that have to be answered are: are the requirements compatible with the available technology and do the requirements unnecessarily drive the design (conflict with system constraints such as weight and power). Addressing these issues requires reviewing previous studies and data for similar systems. Adjustment factors may be appropriate for improvement of technology and for different operating environments, duty cycles, etc. See Topic A11 for Reliability Adjustment Factors.
- 4. Systems with mission critical requirements expressed by the user present difficulties in the requirement development process. Translation models don't account for the nonexponential situations that exist with redundant systems. Because the reliabilities of redundant paths are high compared to serial ones, an approximation can be made that these paths have an equivalent failure rate of zero so that only the remaining serial elements need to be translated.
- 5. The requirement process involves allocation of values to lower levels. In some cases, this is an iterative process requiring several tries to satisfy all requirements. For other cases, the requirements can't be satisfied and dialogue and tradeoffs with the user are required.
- 6. For cases where user needs are not specified it still makes sense to invoke at least a logistics (basic) reliability requirement. In so doing, the contractor has a degree of accountability and is likely to put more effort into designing a reliable system.
- 7. Table R1-3 indicates typical ranges of MTBF for different types of electronic systems.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

13

#### Table R1-3: Typical MTBF Values

Radar Systems	MTBF (Hours)
Ground Rotating Search Radar	100-200
Large Fixed Phase Array Radar	5-10
Tactical Ground Mobile Radar	50-100
Airborne Fighter Fire Control Radar	50-200
Airborne Search Radar	300-500
Airborne Identification Radar	200-2,000
Airborne Navigation Radar	300-4,500

#### **Communications Equipment**

#### MTBF (Hours)

Ground Radio	5,000-20,000
Portable Ground Radio	1,000-3,000
Airborne Radio	500-10,000
Ground Jammer	500-2,000

#### **Ground Computer Equipment**

#### MTBF (Hours)

Workstation	2,000-4,500
Personal Computer (CPU) 286/386/486	1,000-5,000
Monochrome Display	10,000-15,000
Color Display	5,000-10,000
40-100 Megabyte Hard Disk Drive	10,000-20,000
Floppy Disk/Drive	12,000-30,000
Tape Drive	7,500-12,000
CD/ROM	10,000-20,000
Keyboard	30,000-60,000
Dot Matrix, Low Speed, Printer	2,000-4,000
Impact, High Speed, Printer	3,000-12,000
Thermal Printer	10,000-20,000
Plotter	30,000-40,000
Modem	20,000-30,000
Mouse	50,000-200,000
Clock 15	0,000-200,000

#### **Miscellaneous Equipment**

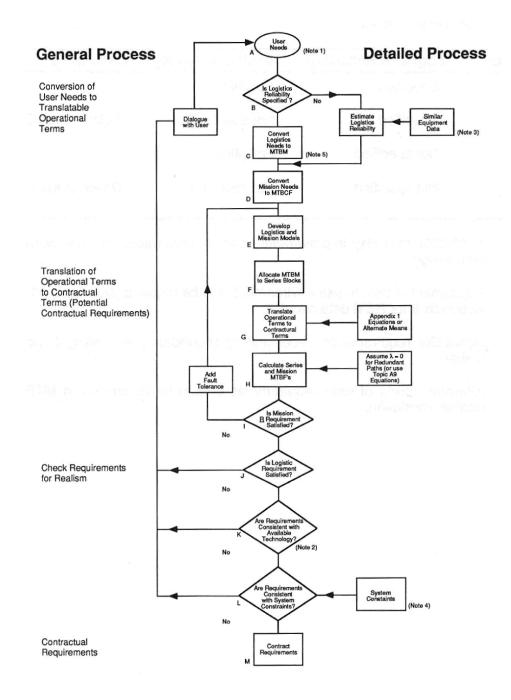

#### MTBF (Hours)

	· · ·
Airborne Countermeasures System	50-300
Airborne Power Supply	2,000-20,000
Ground Power Supply	10,000-50,000
IEEE Bus	50,000-100,000
Ethernet	35,000-50,000

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

14

#### Figure R1-1: Quantitative Reliability Requirement Development Process

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

15

#### Figure R1-1 Notes:

1. User Needs Cases

Case	Logistics Reliability	<b>Mission Reliability</b>	Comments
1	Specified	Specified	
2	Specified	Not specified	Delete steps D, H, I
3	Not specified	Specified	
4	Not specified	Not specified	Delete steps D, H, I

2. A 10-20% reliability improvement factor is reasonable for advancement of technology.

3. Adjustment of data to use environment may be required (see Topic A11). See Appendix 8 for R&M data sources.

4. Reliability requirements necessitating redundancy add weight, cost and power.

5. Alternate forms of user requirements should be converted to MTBM's to enable translation.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

#### **Topic R2: Quantitative Maintainability Requirements**

#### **Scope of Requirements**

Unique maintainability parameters need to be specified for three basic levels of repair:

- **Organizational Level:** Repair at the system location. Usually involves replacing plug-in modules and other items with relatively short isolation and replacement times.
- **Intermediate Level:** Repair at an intermediate shop facility which has more extensive capabilities to repair lower hardware indenture levels.
- **Depot Level:** Highly specialized repair facility capable of making repairs at all hardware indenture levels. Sometimes the original equipment manufacturer.

Recent Air Force policy has promoted the concept of two level maintenance in place of the traditional three level system. Under this concept the classification is:

- **On-equipment:** Maintenance actions accomplished on complete end items.
- **Off-equipment:** In-shop maintenance actions performed on removed components.

Parameters which need to be specified vary with the level of repair being considered. Key maintainability parameters include:

- Mean time to repair (MTTR): Average time required to bring system from a failed state to an operational state. Strictly design dependent. Assumes maintenance personnel and spares are on hand (i.e., does not include logistics delay time). MTTR is used interchangeably with mean corrective maintenance time (Mct).
- Mean maintenance manhours (M-MMH): Total manpower per year (expressed in manhours) required to keep the system operating (not including logistics delay time).
- Mean time to restore system (MTTRS): The average time it takes to restore a system from a failed state to an operable state, including logistics delay time MTTRS = logistics delay time + MTTR). Logistics delay time includes all time to obtain spares and personnel to start the repair.
- **Preventive maintenance (PM):** Time associated with the performance of all required preventive maintenance. Usually expressed in terms of hours per year.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

17

#### **Operational Constraints**

Basic maintainability requirements are determined through an analysis of user operational constraints. Operational constraints include:

- Operating hours per unit calendar time and/or per mission
- Downtime, maintenance time, or availability constraints
- Mobility requirements
- Attended/unattended operation
- Self-sufficiency constraints
- Reaction time
- Operational environment (e.g., chemical, biological and nuclear)
- Skill levels of maintenance personnel
- Manning
- Types of diagnostics and maintenance support equipment which can be made available or implemented (built-in test, manual test equipment, external automatic test equipment, etc.).
- Levels at which repair takes place
- Use of off-the-shelf equipment versus newly designed equipment

#### How to Develop Requirements

The best guidance available is to provide a range of typical values usually applied for each parameter.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

	Organizational	Intermediate	Depot
MTTR	.5 - 1.5 hr	.5 - 3 hr	1 -4 hr
M-MMH	Note 1	Note 1	Note 1
MTTRS	1 - 8 Hrs (Note 2)	NA	NA
PM	2 - 15 hr/yr	NA	NA

Table R2-1: Typ	ical Maintainability Values
-----------------	-----------------------------

#### Notes:

- 1. M-MMH depends on the number of repair visits to be made, the MTTR for each repair visit and the number of maintenance personnel required for each visit. Typical calculations of the mean maintenance manhours per year include:
  - a. Immediate maintenance of a continuously operated system: M-MMH = (8760 hr/yr)/(MTBF) x (MTTR) x (maintenance personnel per repair) + (PM hours per year) x (Maintenance personnel).
  - b. Delayed maintenance of a fault tolerant system: M-MMH = (number of expected repair visits) x (time for each visit) x (maintenance personnel per visit) + (PM hours per year) x (Maintenance personnel).
  - Maintenance of a continuously operated redundant system allowed to operate until failure. M-MMH = (8760 hr/yr)/(MTBCF) x (time for each visit) x (maintenance personnel per visit) + (PM hours per year) x (Maintenance personnel).

Time for each visit is the number of repairs to be made times the MTTR for each repair if repairs are made in series.

2. For unique systems that are highly redundant, MTTRS may be specified as the switch time.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

## Topic R3: Quantitative Testability/Diagnostic Requirements

#### Scope of Requirements

Testability/Diagnostics functions and parameters that apply to each repair level:

- Fault Detection: A process which discovers the existence of faults.
- **Fault Isolation:** Where a fault is known to exist, a process which identifies one or more replaceable units where the fault(s) may be located.
- **False Alarms:** An indication of a fault where no fault exists such as operator error or Built-in Test (BIT) design deficiency.

Testability/Diagnostic requirements are sometimes expressed in the form of rates or fractions such as:

- Fraction of Faults Detected (FFD): The quantity of faults detected by BIT or External Test Equipment (ETE) divided by the quantity of faults detected by all fault detection means (including manual).
  - **System and Equipment Level** FFD is usually weighted by the measured or predicted failure rates of the faults or replaceable units.
  - Microcircuit Level FFD is called fault coverage or fault detection coverage, and all faults are weighted equally. In the fault-tolerant design community, "fault coverage" almost invariably refers to fault recovery coverage. This is usually expressed as the conditional probability that, given a fault has occurred and has been detected, the system will recover.
- Fault Isolation Resolution (FIR): The probability that any detected fault can be isolated by BIT or ETE to an ambiguity group of size "x" or less. (Typically specified for several values of "x").
- False Alarm Rate (FAR): The frequency of occurrence of false alarms.

#### **Scope of Diagnostics**

- **Embedded:** Defined as any portion of the weapon system's diagnostic capability that is an integral part of the prime system.
- **External:** Any portion of the diagnostic capability that is not embedded.
- **Manual:** Testing that requires the use of technical manuals, troubleshooting procedures, and general-purpose test equipment (e.g., voltmeter) by a maintenance technician.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

20

- **Test Program Set (TPS):** The complete collection of data and hardware necessary to test a specific Unit Under Test (UUT) on a specific Automatic Test Equipment (ATE). As a minimum, a TPS consists of:
  - Test vector sets (for a digital UUT)
  - Test application programs (software that executes on the ATE and applies the vectors under the necessary conditions)
  - Test fixtures and ATE configuration files
  - Documentation

A major element of external diagnostics involves the following:

• Automatic Test Equipment (ATE): The apparatus with which the actual UUT will be tested. ATE for digital UUTs has the capability to apply sequences of test vectors under specified timing, loading, and forcing conditions.

#### How to Develop Requirements

In theory, weapon system diagnostic requirements should be developed as an outgrowth of the user developed mission and performance requirements contained in a Mission Need Statement (MNS), Operational Requirements Document (ORD) or similar type document.

The following should also be considered:

- Diagnostic capability realistically achievable with the selected hardware technology and software complexity.
- Tradeoffs involving reliability, maintainability, logistics, weight, power requirements, and system interruption.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

		% Capability	Repair Level
Fault Detection (	All Means)	90-100 100 100	Organizational Intermediate Depot

#### **Topic R6: Contract Data Requirements**

In order for the government to receive outputs from the required contractor performed tasks, the appropriate deliverables must be specified in the Contract Data Requirements List (CDRL). The content of these CDRL items is specified by reference to standard Data Item Descriptions. The timing and frequency of the required reports must be specified in the CDRL.

#### Table R6-1: Data Items & Delivery Dates

#### **Topic R7: R&M Information for Proposals**

Proposal preparation guidance should be provided in the request for proposal (RFP) package to guide the contractor in providing the information most needed to properly evaluate the R&M area during source selection. This is part of the requirements definition process.

Depending on the scope of the R&M requirements specified, information such as the following should be requested for inclusion in the proposal:

- Preliminary R&M analysis/models and estimates of values to be achieved (to at least the line replaceable unit (LRU) level)
- Design approach (including thermal design, parts derating, and parts control)
- R&M organization and its role in the overall program
- Key R&M personnel experience
- Schedules for all R&M tasks
- Description of R&M design guidelines/criteria to be used and trade studies and testing to be performed

#### Note:

It is critical that qualified R&M personnel take part in the actual evaluation of technical proposals. The R&M engineer should make sure this happens by agreement with program management.

Section S Source Selection

Contents

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

29

#### Insight

The criteria for evaluation of contractor proposals has to match the requirements specified in the Request for Proposal (RFP). Contractors must be scored by comparing their proposals to the criteria, not to each other. R&M are generally evaluated as parts of the technical area. The total source selection process includes other nontechnical areas. Air Force policy has emphasized the importance of R&M in the source selection process.

# Topic S1: Proposal Evaluation for Reliability and Maintainability

#### Understanding

- Does the contractor show understanding of the importance of designing in R&M&T in the effort?
- Does the contractor show a firm understanding of R&M&T techniques, methodology, and concepts?
- Does the contractor indicate understanding of the role of testability/diagnostics on maintainability and maintenance?
- Does the contractor understand integrated diagnostics design principles?
- Does the contractor note similar successful R&M&T efforts?

#### Approach

- Management
  - Is an R&M&T manager identified, and are his/her experience and qualifications adequate in light of the scope of the overall program?
  - Are the number and experience of R&M&T personnel assigned to the program, and the number of manhours adequate, judged in accordance with the scope of the overall program?
  - Does the R&M&T group have adequate stature and authority in the organizational framework of the program (e.g., they should not fall under direct control of the design group)?
  - Does the R&M&T group have an effective means of crosstalk and feedback of information between design engineers and higher management?
  - Does the R&M&T manager have adequate control over R&M&T for subcontractors and vendors?
  - Is the testability diagnostics function integrated into the R&M program?

Does the contractor utilize concurrent engineering practices and is the R&M&T group represented on the team?

- Design
  - Are design standards, guidelines and criteria such as part derating, thermal design, modular construction, Environmental Stress Screening (ESS), and testability cited?

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

31

- Is the contractor's failure reporting and corrective action system (FRACAS) a closed loop controlled process?
- Is there a commitment to the required parts control program (e.g., MIL-M-38510, MIL-STD-883, etc.)? Are approval procedures described/ proposed for nonstandard parts?
- Are system design reviews (internal and external) required regularly?
- Are tradeoff studies proposed for critical design areas?
- Is a time-phasing of R&M&T tasks provided along with key program milestones?
- Are areas of R&M&T risk identified and discussed?
- Does the contractor include consideration of software reliability?
- Does the contractor describe his plan for testability/diagnostics design and the potential impacts on reliability and maintainability?
- Does the contractor identify tools to be used to generate test vectors and other diagnostic procedures for BIT and ATE (automatic test equipment)?

#### Analysis/Test

- Are methods of analysis and math models presented?
- Are the R&M&T prediction and allocation procedures described?
- Has the time phasing of the R&M&T testing been discussed, and is it consistent with the overall program schedule?
- Is adequate time available for the test type required (such as maximum time for sequential test)?
- Is the ESS program consistent with the requirements in terms of methodology and scheduling?
- Does the contractor make a commitment to predict the design requirement MTBF prior to the start of testing?
- Are the resources (test chambers, special equipment, etc.) needed to perform all required testing identified and, is a commitment made to their availability?

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

Qu**ART<sup>PRO</sup>** Quanterion Automated Reliability Toolkit

#### Compliance

#### Design

- Does the contractor indicate compliance with all required military specifications for reliability, maintainability and testability?
- Is adequate justification (models, preliminary estimates, data sources, etc.) provided to backup the claims of meeting R&M&T requirements?
- Is there an explicit commitment to meet any ease of maintenance and preventive maintenance requirements?
- Is there an explicit commitment to meet the Built-in-Test (BIT)/Faultisolation Test (FIT) requirements (Fraction of Faults Detected (FFD), Fault Isolation Resolution (FIR) and False Alarm Rate (FAR) )?
- Is each equipment environmental limitation specified and do these conditions satisfy the system requirements?
- Are all removable modules keyed?
- Will derating requirements be adhered to and are methods of verifying derating requirements discussed?

#### Analysis/Test

- Is a commitment made to perform a detailed thermal analysis?
- Will the contractor comply with all R&M&T required analyses?
- Is there an explicit commitment to perform all required environmental stress screening?
- Does the contractor comply with all system level R&M&T test requirements? Will the contractor demonstrate the R&M&T figures of merit (MTBF, MTTR, FFD, FIR and FAR) using the specified accept/reject criteria?
- Does the contractor comply with the specification (or other commonly specified) failure definitions?
- Does the contractor agree to perform thermal verification tests and derating verification tests?
- Data
  - Is there an explicit commitment to deliver and comply with all of the required R&M&T data items?

## Insight

Proven design approaches are critical to system R&M success. For many programs the government requires that certain approaches be used (such as a particular level of part stress derating). Other programs allow the contractor to develop and use his own design criteria as long as his end product design meets the government requirements or is subject to provisions of product performance agreements (guarantees, warranties, etc.). Regardless of the situation, the R&M engineer must actively evaluate the contractor design progress.

## Topic D1: Part Stress Derating

The practice of limiting electrical, thermal and mechanical stresses on parts to levels below their specified ratings is called derating. If a system is expected to be reliable, one of the major contributing factors must be a conservative design approach incorporating realistic derating of parts. Table D1-1 defines the key factors for determining the appropriate level of derating for the given system constraints. Table D1-2 indicates the specific derating factors for each part type.

Factors		Score
Reliability Challenge	<ul> <li>For proven design, achievable with standard parts/circuits</li> </ul>	1
entanongo	• For high reliability requirements, <i>special design features</i> needed	2
	<ul> <li>For new design challenging the state-of-the-art, new concept</li> </ul>	3
System Repair	• For <i>easily accessible</i> , quickly and economically repaired systems	1
	• For high repair cost, limited access, <i>high skill levels required,</i> very low downtimes allowable	2
	For <i>nonaccessible repair</i> , or economically unjustifiable repairs	3
Safety	• For routine safety program, no expected problems	1
	• For potential system or equipment high cost damage	2
	• For potential <i>jeopardization of life</i> of personnel	3
Size, Weight	• For no significant design limitation, standard practices	1
	<ul> <li>For special design features needed, difficult requirements</li> </ul>	2
	• For new concepts needed, severe design limitation	3
Life Cycle	• For <i>economical repairs,</i> no unusual spare part costs expected	1
	• For potentially high repair cost or unique cost spares	2
	• For systems that may require <i>complete substitution</i>	3

Instructions: Select score for each factor, sum and determine derating level or parameter.

Derating Level	Total Score
I	11 - 15
II	7 - 10
III	6 or less

**Microcircuits:** This derating criteria is based on available data and is limited to: 60,000 gates for digital devices, 10,000 transistors for linear devices, and 1 Mbit for memory devices. Microcircuits should not exceed supplier minimum or maximum rating for supply voltage, 125°C junction temperature (except GaAs), or supplier maximum.

## Topic D2: Thermal Design

One of the important variables in system reliability is temperature. Therefore, the thermal design of a system must be planned and evaluated. Full discussion of this topic is beyond the scope of this document but it is important to point out to a reliability engineer what limitations there are for common thermal design approaches. Table D2-1 summarizes fundamental thermal design issues which should be addressed during system development. Table D2-2 summarizes the most common cooling techniques for electronics and their limitations. Analysis Topic A14 provides a basic method of estimating microcircuit junction temperatures for these cooling techniques.

#### Table D2-1: Thermal Design Issues

\_

Issue	Concern
• Thermal Requirements: Has a thermal analysis requirement been incorporated into the system specification?	If not specified, a formal analysis probably will not be performed and there will be no possibility of independent review.
<ul> <li>Cooling Allocation: Has cooling been allocated down to each subsystem, box and LRU.</li> </ul>	Cooling allocations should be made to the box level (or below) and refined as the thermal design matures.
• <b>Preliminary Thermal Analysis:</b> Has a preliminary analysis been performed using the manufacturer's specifications for power outputs?	This usually represents the worst case because manufacturers specify maximum power dissipations.
• <b>Detailed Thermal Analysis:</b> Has a detailed analysis been performed using actual power dissipations?	The preliminary analysis needs to be refined using actual power dissipations. Results need to feed into reliability predictions and derating analysis.
<ul> <li>Thermal Analysis Assumptions:</li> <li>Have junction-to-case thermal resistance values been fully justified?</li> </ul>	Optimistic values can have a significant effect on results. Thermal resistances from MIL-M-38510 should be used unless other values are justified.
<ul> <li>Does the thermal analysis make use of junction-to-ambient thermal resistances?</li> </ul>	Junction-to-ambient values should not be used since they are highly dependent on coolant flow conditions.
<ul> <li>Are all modes and paths of heat transfer considered in the analysis?</li> </ul>	The three modes are convection, conduction, and radiation. Rationale should be provided for omitting any

heat transfer modes or paths.

#### Table D2-2: Cooling Technique Limitations

**Example:** A 9" x 5" printed circuit board using free convection cooling would be limited to about 22.5 watts.

45

## **Topic D3: Parts Control**

Managing a parts control program is a highly specialized activity and does not typically fall under the system's R&M engineer's responsibility. However, because of the interrelationship of parts control and good system reliability, it is important that R&M engineers and program managers have a general understanding of the parts control discipline. Parts control questions which are often asked include:

- Why do parts control?
- What are the various "tools" to accomplish parts control?
- What is a military specification "Mil-Spec" qualified part, a MIL-STD-883 part, a Standard Military Drawing (SMD) part, and a vendor equivalent part?

Why do parts control? Since the invention of semiconductors, users could never be sure that a device purchased from one manufacturer would be an exact replacement for the same device obtained from another supplier. Major differences in device processing and electrical testing existed among suppliers. Because of the importance of semiconductors to military programs, the government introduced standard methods of testing and screening devices in 1968. Devices which were tested and screened to these methods were then placed on a government approval list called the qualified parts list (QPL). Through this screening and testing process, a part with known quality and performance characteristics is produced. The philosophy for assuring quality product has evolved since 1968 and now there are two methodologies in place, the original QPL program and the new Qualified Manufacturer's List (QML) program (established 1985). The QML approach defines a procedure that certifies and gualifies the manufacturing processes and materials of potential vendors as opposed to the individual gualification of devices (QPL). Hence, all devices produced and tested using the QML certified/gualified technology flow are qualified products. Part's technology flows qualified to this system are listed on the Qualified Manufacturer's List. Both Hybrids as well as monolithic microcircuits are covered under this system.

What are the various "tools" to accomplish parts control? The government has subdivided parts into three basic classifications: (1) microelectronics, (2) semiconductors (e.g. transistors, diodes, etc.) and (3) electrical parts (e.g. switches, connectors, capacitors, resistors, etc.). For each class, part specification and test method documents have been developed. Table D3-1 summarizes key documents and their content.

What is a military specification "Mil-Spec" qualified part, a MIL-STD-883 part, a Standard Military Drawing (SMD) part, and a vendor equivalent part? The primary difference in these descriptions is that each of these part classes has undergone different levels of screening and certification. Certification involves specifying and documenting the part manufacturing process. It also involves government and manufacturer agreement on a detailed part specification. This ensures consistent part quality and known performance. Table D3-2 summarizes

ROME LABORATORY'S RELIABILITY ENGINEER'S TOOLKIT

common classes of parts and what these classifications signify. Table D3-3 summarizes MIL-STD-883D screening procedures and is included to give the reader a feel for the wide range of tests required. These screening requirements are similar for the respective systems defined in Table D3-2. Topic A11, Table A11-1 shows the impact of the various part designations on system reliability.

Document	Title	Content
MIL-M-38510	General Specification for Microcircuits	Provides detailed specification requirements in the form of "slash sheets" for several hundred of the most commonly used microcircuits. Covers screening requirements (referenced to MIL-STD-883), electrical testing, quality conformance, physical dimensions, configuration control for critical manufacturing processing steps and production line certification.
MIL-I-38535	General Specification for Integrated Circuits (Microcircuits) Manufacturing	Provides detailed specification requirements in the form of standard military drawings (SMDs). Quality assurance requirements are defined for all microcircuits built on a manufacturing line which is controlled through a manufacturer's quality manage- ment program and has been certified and qualified in accordance with the require- ments specified. The manufacturing line must be a stable process flow for all microcircuits. Two levels of product assurance (including radiation hardness assurance) are provided for in this specification, avionics and space. The certification and qualification sections specified outline the requirements to be met by a manufacturer to be listed on a Qualified Manufacturer's List (QML). After listing of a technology flow on a QML, the manufacturer must continually meet or improve the established baseline of certified and qualified procedures through his quality management program and the technology review board.

 Table D3-1: Key Parts Control Documents and Their Content

ROME LABORATORY'S RELIABILITY ENGINEER'S TOOLKIT

47

Document	Title	Content
MIL-H-38534	General Specification for Hybrid Microcircuits	Provides detailed specification requirements in the form of Standard Military Drawings (SMDs) for standard hybrid products, and Source Control Drawings (SCDs) using the SMD boilerplate for custom hybrids. Covers requirements for screening (referenced to MIL-STD-883) quality conformance inspections, configuration control, rework limitations and manufacturing line certification procedures.
MIL-STD-883	Test Methods and Procedures for Microelectronics	Provides uniform methods and procedures for testing microelectronic devices. Structured into five classes of test methods: 1000 class addresses environmental tests, 2000 class addresses mechanical tests, 3000 class addresses electrical tests for digital circuits, 4000 class addresses electrical tests for linear circuits, and 5000 class addresses test procedures. The tests covered include moisture resistance, seal test, neutron irradiation, shock and acceleration tests, dimensional tests, input/output current tests, and screening test procedures to name a few. Two test levels are described: Class B (Class H, MIL-H- 38534/Class Q, MIL-I-38535) and Class S (Class K, MIL-H-38534/Class V, MIL-I- 38535). Class S is geared toward space qualified parts and requires a host of tests not performed on Class B parts (e.g. wafer lot acceptance, 100% nondestructive bond pull, particle impact noise detection, serialization, etc.).
MIL-S-19500	General Specification for Semiconductors	Provides detailed specification sheets establishing general and specific requirements including electrical characteristics, mechanical characteristics, qualification requirements, inspection procedures and test methods.

48

Document	Title	Content
MIL-STD-750	Test Methods for Semiconductor Devices	Provides uniform methods and procedures for testing semiconductors. Structured into five classes of test methods: 1000 class addresses environmental tests, 2000 class addresses mechanical characteristics, 3000 class addresses electrical characteristics, 3100 class addresses circuit performance and thermal resistance measurements, and the 3200 class addresses low frequency tests.
MIL-STD-202	Test Methods for Electronic and Electrical Parts	Provides uniform methods for testing electronic and electrical parts. Structured into three classes of test methods: 100 class addresses environmental tests, 200 class addresses physical characteristic tests and 300 class addresses electrical characteristic tests. These tests are not tied to a single part specification document as with microelectronics and semiconductors, but rather, numerous specifications for various component types.
MIL-STD-965	Parts Control Program	Provides control procedures to be used in the design and development of military equipment, including the submission, review and approval of a Program Parts Selection List. Generally, an overall guide for the implementation and management of a parts control program. The document provides for two basic management procedures. Procedure I is applicable to a majority of programs and does not make use of a formal parts control board. Procedure II requires a formal parts control board and is recommended for consideration where there is an aggregation of contractor/ subcontractors.

49

Part Classification	Part Classification Description
JAN or MIL-M-38510 Parts	These parts have a detailed specification (slash sheet) in MIL-M-38510 which controls all mechanical, electrical, and functional parameters of the part. Additionally, the manufacturing process flow is certified by DoD's Defense Electronics Supply Center (DESC), the devices are screened to MIL-STD-883 test method requirements, and are subjected to rigorous quality conformance testing. A manufacturer, once certified by DESC, can then qualify products to the specification and have these products listed on the qualified products list. The product specification (performance and mechanical) is contained in a M38510/0000 "slash sheet" or one part number SMD. Standardization is achieved through many manufacturers building product to the same "one part SMD" or "slash sheet" and testing them using the standard test methods found in MIL-STD-883.
QML (Qualified Manufacturers Listing) or MIL-I-38535 Parts	Device performance requirements (electrical, thermal, and mechanical) are detailed in the Standard Military Drawing (SMD). The qualifying activity or its agent certifies and qualifies the manufacturers process flows. Once certified and qualified, the manufacturer may produce multiple device types on that flow as MIL-I-38535 compliant parts. Since the process is considered qualified, individual products do not have to be qualified individually for selected quality conformance inspections, except Class V (Space) product. Where standard tests are used by the manufacturer to qualify the process, the use of American Society for Testing and Materials (ASTM), MIL-STD-883 or Joint Electron Device Engineering Council (JEDEC) specifications are suggested. The manufacturers are required to identify a Technical Review Board (TRB) within their company. It is the duty of the TRB to approve all changes in the process and report to DESC on a regular basis. Changes in the process and products are reviewed annually by a team of users, the qualifying activity and the preparing activity. Progress in meeting company established yield, Statistical Process Control (SPC), and reliability goals are reported at this meeting. Parts produced under MIL-I-38535 are listed on the QML.

## Table D3-2: Microelectronics Classifications and Descriptions

ROME LABORATORY'S RELIABILITY ENGINEER'S TOOLKIT

Part Classification	Part Classification Description
QML (Hybrids) / CH or MIL-H-38534 Parts	The requirements for a hybrid microcircuit are set forth in Standard Military Drawings (SMDs) or Source Control Drawings (SCDs). The qualifying activity qualifies the manufacturer's process flows and once certified and qualified may produce multiple device types on that flow as MIL-H-38534 compliant parts. Test methods are defined in MIL- STD-883. All major changes to the process flows require qualifying activity approval. Parts produced under this system are listed in the Qualified Manufacturer's List.
Standard Military Drawing (Class M) and MIL-STD-883 Compliant Devices	This system evolved from various manufacturer's in-house versions of Test Methods 5004 and 5005 of MIL-STD-883. It was an informal and inconsistent system in the late 70's and early 80's known as MIL equivalent, or look alikes. Manufacturers were falsely advertising these parts as equivalent to JAN parts, without basis, because most critical JAN requirements (e.g. audits, qualification, quality conformance inspection tests) were not followed. In some cases, not all the required JAN testing was being performed by the manufacturer. This resulted in the government incorporating a truth in advertising paragraph in MIL-STD-883 (i.e. Paragraph 1.2.1). This required the manufacturer to self-certify that all 1.2.1 requirements, a subset of the MIL-M-38510 requirements, were being met if advertised as meeting MIL-STD-883 requirements. DESC has begun an audit program to verify the manufacturers self compliance to MIL-STD-883, Paragraph 1.2.1 compliant product. The primary difference between Standardized Military Drawing (SMD) product and MIL-STD-883 compliant product is that SMD (Class M) sources are approved by the Defense Electronics Supply Center (DESC). DESC manages the procurement document (SMD) and approves the sources by accepting their certificate of compliance to the Paragraph 1.2.1 requirements. The MIL-STD-883 compliant product is produced to uncontrolled vendor data books and the government has no control over compliancy claims. Certification and qualification by DESC is not required for either system.

51

Part Classification	Part Classification Description
Vendor Equivalent Parts	Each parts supplier has a set of commercial specifications which they use for manufacturing product for general sale. Usually the product specifications are included on a data sheet which is then collected into a catalog for sale to the general public. There is a wide spectrum of quality available depending on the quality standards applied by the company. Generally, these parts have been tested to the vendor's equivalent MIL-STD-883 test methodology. The vendor may or may not modify the scope of the tests and a careful analysis is required to determine how similar the vendor's tests are to MIL-STD-883 tests.

DESIGN - TOPIC D4

## **Topic D4: Review Questions**

Program and design reviews are key vehicles for measuring development progress and preventing costly redesigns. Participation by government individuals knowledgeable in R&M is critical to provoking discussions that bring out the issues important to R&M success. Of course, the questions to be posed to the development contractor depend on the timing of the review as indicated below. Action Items should be assigned at the reviews based on open R&M issues and the reliability engineer must follow-up to ensure that they're resolved satisfactorily.

#### Table D4-1: Major Program Reviews

Review	Purpose	R&M Engineers Role	
System Requirements Review (SRR)	To ensure a complete understanding of system specification and statement of work requirements. This is usually done by means of a detailed expansion and review of the contractor's technical proposal.	Discuss the performance of all required R&M tasks and requirements with contractor R&M personnel. Topics such as the contractor's overall reliability program plan, data items and delivery schedule are usually discussed.	
Preliminary Design Review (PDR)	To evaluate progress and technical adequacy of the selected design approach prior to the detailed design process.	Review preliminary R&M modeling, allocations and predictions to ensure adequacy in meeting R&M requirements. Discuss status of other R&M tasks such as parts control, derating, thermal design and reliability critical items.	
Critical Design Review (CDR)	To ensure that the detailed design satisfies the requirements of the system specification before freezing the design for production or field testing.	Review the final reliability analysis and modeling to ensure R&M requirements are met. Discuss parts control program status and military part procurement lead time requirements. Review adequacy of the final thermal analysis and derating. Discuss R&M testing.	
Test Readiness Review (TRR)	To ensure that all CDR problems have been satisfactorily resolved and to determine if the design is mature enough to start formal testing.	procedures to ensure acceptable ground rules and compliance with	
Production Readiness Review (PRR)	To review test results and determine whether or not the design is satisfactory for production.	Discuss R&M testing results and ensure any design deficiencies found during testing have been corrected. Discuss production quality assurance measures.	

#### ROME LABORATORY'S RELIABILITY ENGINEER'S TOOLKIT

55

	Review Where Usually Most Applicable	
Question	SRR PDR CDR TRR PRR	Remarks
R&M Management		
What are the avenues of technical interchange between the R&M group and other engineering groups (e.g., Design, Systems Engineering, ILS, Procurement, and Test and Evaluation)?	X X	R&M engineering should participate at all engineering group meetings where R&M is effected. Easy avenues of technical interchange between the electrical design group and other groups such as thermal engineering must exist.
Does the reliability group have membership and a voice in decisions of the Material Review Board, Failure Review Board, and Engineering Change Review Board?	x x x x	Membership or an option to voice an opinion is essential if the failure tracking and corrective action loop is to be completed.
Is the contractor and subcontractor(s) a member of the Government Industry Data Exchange Program (GIDEP)? What is the procedure for comparing parts on the ALERT list to parts used in the system?	X X X	Incoming part types should be checked against the GIDEP ALERT data base and incoming ALERTS should be checked against the system parts list. (GIDEP ALERTS are notices of deficient parts, materials or processes).
Are reliability critical items given special attention in the form of special analysis, testing or destructive laboratory evaluation?	X X	Critical parts are usually defined by contract or by MIL-STD-785. Methods of tracking critical parts must be identified by the contractor. See Topic D5 for a critical items checklist.
Do the purchase orders require vendors to deliver specified levels of R&M&T based on allocation of higher	x x	Requirements should include verification by analysis or test.

## Table D4-2: Design Review Checklist

ROME LABORATORY'S RELIABILITY ENGINEER'S TOOLKIT

56

level requirements?

Question		Appl	/here l icable CDR	•	ly PRR	Remarks
Does the reliability group have access to component and failure analysis experts and how are they integrated into the program?	Х	Х	Х			Failure analysis is essential to determine the cause and effect of failed components.
Is there adequate communication between testability design engineers and the electrical design group to ensure that testability considerations are worked into the upfront design?	х	Х				
Are JAN microcircuits (MIL- M-38510 or MIL-I-38535) and semiconductors (MIL-S- 19500) being used wherever possible and are procurement lead times for these devices adequate?		X	х			Part quality in order of preference: MIL-M-38510, or MIL-I-38535 devices; MIL- STD-883 Class B; MIL-STD- 883 vendor equivalent; commercial hermetically sealed. JAN parts usually require longer procurement times (3 to 6 months) which sometimes causes commercial parts to be forced into the design.
Where nonstandard parts are used, are they procured via a specification control drawing (SCD) and do they have at least two suppliers? Are methods for nonstandard part approval clearly established and is there a clear understanding of what constitutes a standard and nonstandard part?	X	Х	х			Specification control drawings should specify reliability, environment and testing requirements.
Has an up-to-date preferred parts selection list (PPSL) been established for use by designers?	х	Х				DESC and DISC establish baseline PPSLs which should be the basis of the contractor's list.

57

	Review V		ly	
Question	Most App SRR PDR		PRR	Remarks
R&M Design				
Do the R&M&T models accurately reflect the system configuration, its modes of operation, duty cycles, and implementation of fault tolerance?	X	Х		
Do predictions meet numerical R&M specification requirements? Are prediction procedures in accordance with requirements?	x x	Х		If not, better cooling, part quality and/ or redundancy should be considered.
Have R&M allocations been made to the LRU level or below? Do reliability pre- dictions compare favorably to the allocation?	x x			Weighted reliability allocations should be made to lower levels based on the upper test MTBF ( $\theta_0$ ), or similar measure.
Does the testability analysis show that numerical testability requirements will be met for the organizational, intermediate and depot repair levels?	х	Х		If not, alternate design concepts must consider including more automated features.
Have tradeoff studies been performed in the areas of R&M&T?	x x			Typical tradeoffs might include redundancy levels, weight, power, volume, complexity, acquisition cost, life cycle cost.
Has a thermal analysis been performed to ensure an adequate cooling technique is used and have the temperature results been factored into the reliability analysis?	x	х		Thermal analysis is essential to a complete program.
Has piece part placement been analyzed to ensure that high dissipating parts are placed away from heat sensitive parts?	Х	Х		For example, high power dissipation components such as large power resistors, diodes and transformers should be investigated.

58

		w Wh Applic	ere Us	ually	
Question		PDR C		RR PRR	Remarks
Have methods been established to ensure that operating temperatures of off-the-shelf equipment will be within specified limits?	Х	Х			Reference environmental requirements in the system specification.
Do parts used in the design meet system environmental requirements?		Х	Х		Temperature range for most military parts is - 55°C to + 125°C. Temperature range for most commercial parts (plastic) is 0°C to 70°C.
Is there a clearly established derating criteria for all part types used in the design and is there a clear procedure for monitoring and enforcing this criteria?	Х	х	Х		The part derating levels are a function of program type but should be at least Level III in Topic D1.
Are temperature overheat sensors included in the system design?		х	Х		
Is there a clear procedure for the identification of parts not meeting the derating criteria?	х	Х	Х		A tradeoff analysis should be performed on parts not meeting derating criteria to determine if a redesign to lower stress is appropriate.
Will part derating verification tests be performed?				Х	Depending on system criticality, 3 to 7 percent of the system's parts should undergo stress verification. No more than 30 percent of the tested parts should be passive parts (resistors, capacitors, etc.).
Have limited life parts and preventive maintenance tasks been identified, and inspection and replacement requirements specified?		×	X		For example, inspection items may include waveguide couplers, rotary joints, switches, bearings, tubes and connectors. Typical Preventive Maintenance (PM) items include air filters, lubrication, oil changes, batteries, belts, etc.

59

	Review V	Vhere	Usual	ly	
Question	Most App	licable	)		
	SRR PDR	CDR	TRR	PRR	Remarks
Have single points of failure been identified, and their effects determined?	X	х			Important for identifying areas where redundancy should be implemented and to assist in ranking the most serious failure modes for establishing a critical items list.
Have compensating features been identified for those single points of failure where complete elimination of the failure mode is impractical?	Х	х			Compensating features could include increased part quality, increased testability, additional screening, fail safe design provisions, etc.
Have areas where fault ambiguity may exist been identified? Have alternative methods of isolation and checkout (e.g., semi- automatic, manual, repetitive replacement, etc.) been identified for these areas?	x	x			Additional test nodes must be considered to break ambiguity groups.
For each maintenance level, has a decision been made for each item on how built-in- test, automatic test equipment, and general purpose electronic test equipment will support fault detection and isolation?	x	х			
Are features being incorporated into the testability design to control false alarms?	х	x			Typical features might include definition of test tolerances, transient monitor- ing and control, multiple run decision logic, environmental effects filtering and identification, etc.
<b>R&amp;M Testing</b> Is there a failure reporting and corrective action system (FRACAS) in place, and does it account for failures occurring during all phases of testing?		х	Х	×	FRACAS should include data from incoming inspection, development testing, equip- ment integration testing and R&M testing. FRACAS should be "closed loop" emphasizing corrective action.

60

0	Review V Most App	licable	)		
Question	SRR PDR	CDR	TRR F	PRR	Remarks
Is there a failure analysis capability and will failures be subjected to a detailed analysis?		х	Х	Х	Contractor should identify criteria used to determine which failures will be analyzed.
Are subcontractors subjected to the same FRACAS requirements, and will their failure analysis reports be included with the prime contractor's reports?	х		Х	х	
Does the reliability demon- stration test simulate the operating profile seen in the field and will all modes of equipment operation be tested over the required environmental extremes?		x	х		The test must simulate the operational profile and modes to have valid results.
Does the maintainability and testability demonstration test simulate realistic failures and is the candidate task list sufficient to reduce bias?		х	х		Candidate lists should be four to ten times the size o the test sample.
Are relevant and nonrelevant failure definitions clear and agreed upon?		Х	х		See Topic T9 for failure definitions.
Are equipment performance checks to be performed during testing clearly defined and has the information to be recorded in the test log been clearly defined and agreed upon?			х		Items such as temperature variations, start/stop or vibration, event occurrence times and a detailed des- cription of system recovery after failure should be included as a minimum.
Do preliminary plans for ESS meet the required needs?			Х	x	Temp. and random vibration are the most effective screens. At module level perform 20 to 40 temp cycles per module. At higher assembly levels, perform 4 to 20 cycles. (See RADC-TR- 86-149, "ESS" and DOD- HDBK-344, "Environmenta Stress Screening of Elect- ronic Equipment," and Topics T1-T3 for guidance).

61

## **Topic D5: Critical Item Checklist**

Major Concerns	Comments			
• Has the contractor developed formal policies and procedures for identification and control?	<ul> <li>Policies should be distributed to design, manufacturing, inspection and test personnel.</li> </ul>			
• Are the procedures implemented at the initial design stage and do they continue through final acceptance period?	<ul> <li>The program has to start early so that safety related items can be minimized.</li> </ul>			
<ul> <li>Are periodic reviews planned to update the list and controls?</li> </ul>	<ul> <li>Reviews at SRR, PDR, and CDR must be considered.</li> </ul>			
<ul> <li>Has an FMEA been performed on each critical item?</li> </ul>	<ul> <li>Failure modes need to be identified so that control procedures can be developed.</li> </ul>			
<ul> <li>Are compensating features included in the design?</li> </ul>	<ul> <li>Features such as safety margins, overstress testing, special checkouts should be considered.</li> </ul>			
• Does the contractor's control plan eliminate or minimize the reliability risk?	• Development of a list of critical items is only half the solution; controls such as stress tests, design margins, duty cycles, and others must be considered.			
<ul> <li>As a minimum, are the following criticality factors considered:</li> </ul>	• A list of critical items, personnel responsible for monitoring and controlling, and review procedures must be established. Other application unique critical items should be identified by the procuring activity.			
- Failures jeopardizing safety				
- Restrictions on limited useful life				
- Design exceeding derating limits				
- Single sources for parts				
- Historically failure prone items				
<ul> <li>Stringent tolerances for manufacturing or performance</li> </ul>				
<ul> <li>Single failure points that disrupt mission performance</li> </ul>

## **Topic D6: Dormancy Design Control**

Dormancy design control is important in the life cycle of a weapon system because, after an equipment has been installed or stored in an arsenal, the predominant portion of its life cycle is in the dormant mode. The main problems are the lack of dormancy related design guides and control methods to maintain or assure system reliability in storage. Questions often asked and seldom answered are:

- **Most important stresses?** Mechanical, chemical, and low thermal; the synergism of these three stresses is critical.
- **Most significant failure mechanisms?** Failures related to latent manufacturing defects, corrosion, and mechanical fracture, with most failures being the result of latent manufacturing defects rather than specific aging mechanisms.
- **Types of failure?** Most failures that occur during nonoperating periods are of the same basic kind as those found in the operating mode, though precipitated at a slower rate.
- **Most important factor?** Moisture is the single most important factor affecting long term nonoperating reliability. All possible steps should be taken to eliminate it from electronic devices. Hygroscopic materials should be avoided or protected against accumulation of excess moisture.
- **Materials to avoid?** Avoid materials sensitive to cold flow and creep as well as metalized and non-metallic finishes which have flaking characteristics. Avoid the use of lubricants; if required, use dry lubricants such as graphite. Do not use teflon gaskets in lieu of conventional rubber gaskets or better yet, use silicone based rubber gaskets.

#### **Storage Guidelines**

- **Do not test the equipment:** Periodic testing results in failures rather than higher states of readiness. Historical data on missile systems that were stored and tested periodically shows that failures were introduced into the equipment as a result of the testing process. Causes of the failures were test procedures, test equipment and operator errors. Main guidelines are:
  - Disconnect all power
  - Ground all units and components
  - **Pressurize all coax waveguides:** Use nitrogen to prevent moisture and corrosion.
  - **Maintain temperature at 50°F +/- 5°F:** At least drain all equipment of water to prevent freezing or broken pipes.
  - **Control relative humidity to 50% +/- 5%:** Reduces corrosion and prevents electrostatic discharge failure.
  - Periodically recharge batteries

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

63

- **Protect against rodents:** Squirrels have chewed cables, mice have nested in electronic cabinets and porcupines have destroyed support structures (wood). Door/window seals, traps/poison and frequent inspection protect against these rodents.

#### **Protective and Control Measures**

#### Materials

- **Mechanical items:** Use proper finishes for materials, nonabsorbent materials for gasketing, sealing of lubricated surfaces and assemblies, and drain holes for water run-off.
- Electronic and electrical items: Use nonporous insulating materials, impregnate cut edges on plastic with moisture resistant varnish or resin, seal components with moving parts and perforate sleeving over cabled wire to avoid the accumulation of condensation.
- **Electromagnetic items:** Impregnation of windings with moisture proof varnish, encapsulation, or hermetic sealing, and use of alumina insulators.
- Thermal items: Use nonhygroscopic materials and hermetic sealing.
- **Finishes:** Avoidance of hygroscopic or porous materials; impregnate all capillary edges with wax, varnish or resin.

#### Parts

- Use parts with histories of demonstrated successful aging.
- Use only hermetically sealed semiconductors.
- Do not use semiconductors and microcircuits that contain nichromedeposited resistors.
- Select parts that use mono-metallization to avoid galvanic corrosion.
- Do not seal chlorine or other halogen-containing materials within any circuitry components.
- Avoid the use of variable resistors, capacitors, inductors, or potentiometers.
- Avoid the use of electromechanical relays.
- Avoid attachments and connections that depend on spring action for effectiveness.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

## Topic D7: Surface Mount Technology (SMT) Design

SMT involves placing a component directly onto the surface of a printed circuit board (PCB) and soldering its connections in place. SMT components can be active (integrated circuits) or passive devices (resistors), and can have different lead designs as presented below. In either case, the solder connection is both an electrical and mechanical connection, thus replacing the mechanical connection associated with plated through holes (PTH). Maximizing the integrity of SMT designs centers around minimizing the thermal and mechanical fatigue of both the component's solder connection and the board's PTHs.

### **Common Lead Designs**

**Leadless Chip Carriers (LCCs):** Attaching component to board directly with solder alone.

Leaded Chip Carrier: Attaching a leaded component to board with solder.

**CTE:** Coefficient of Thermal Expansion is the change in length per unit length when heated through one degree. It directly effects the thermal strain and thus the stress in the solder joint.

### **Design Guidelines**

- Use the largest allowable standard size for passive components to minimize manufacturing flaws.
- Carefully consider the application for active devices when electing to use leadless versus leaded components.
- Use special CTE matching to preclude stress cracking in LCC solder joints.
- Minimize PCB to 13" x 13" size to avoid warp and twist problems.
- Provide an adequate clearance at the board's edge in order to provide space for the board mounting and wave solder conveyor fingers.
- Locate components on a grid to ease programming of automatic dispensing or placement equipment.
- Allow proper spacing between components to account for visual inspection, rework, and engineering changes to assembly.

## **Topic D8: Power Supply Design Checklist**

For many years power supply reliability has fallen short of expectations especially when used in adverse environments. Today the situation is even worse as power supplies are being designed to exceed three watts per cubic inch - a challenge to construction and packaging techniques and part technology. And, since high density means more concentrated heat - the enemy of all components - power supply reliability problems will prevail. Following are design considerations and possible solutions to review:

Items to be Addressed	Solutions/Recommendations		
<ul> <li>Transient effects</li> <li>In-rush current</li> </ul>	<ul> <li>Apply resistor-triac technique, thermistor technique</li> </ul>		
- High-voltage spikes	Apply metal oxide varistor (MOV) transient voltage suppressor		
- Short circuits	Apply constant current and current foldback protection		
- Switching voltage transients	Apply snubber circuits		
Effects of AC ripple current	Consider use of MIL-C-39006/22 capacitors		
Corrosion due to leakage	• Avoid wet slug tantalum capacitors and use plating and protective finishes		
Aluminum electrolytic capacitors	<ul> <li>Epoxy end-seals minimize external contamination</li> </ul>		
<ul> <li>Temperature stability</li> </ul>	Use low temperature coefficient capacitors (mica or ceramic)		
<ul> <li>Packaging techniques</li> </ul>	<ul> <li>Enhance heat transfer, control electromagnetic interference, decrease parasitic capacitance</li> </ul>		
Saturation	Use antisaturation diodes (Baker Clamps) in conjunction with a switching transistor		
Potentiometers	Replace with precision fixed resistor		
<ul> <li>Short mounting leads</li> </ul>	• Derate the operating voltage below 50% to prevent hot spots		

### Table D8-1: Design Checklist (New Designs)

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

Items to be Addressed	Solutions/Recommendations
Static discharge damage	<ul> <li>Use antistatic grounds for manufacturing and maintenance</li> </ul>
<ul> <li>Field effect transistor (FET) versus bipolar device</li> </ul>	<ul> <li>FET's increase switching speeds but reduce drive capability</li> </ul>
Junction temperatures	• Do not exceed 110°C
Mechanical stresses	<ul> <li>Use of vibration isolators/shock mountings, parts spaced to prevent contact during shock &amp; vibration</li> </ul>
Solder joint process	<ul> <li>95%(goal) of solder joints should be made via automated process</li> </ul>
Cooling	<ul> <li>Conductive cooling to a heat exchanger is preferred</li> </ul>

## Table D8-2: Design Checklist (Commercial Designs)

Items to be Addressed	Solutions/Recommendations
Part quality	<ul> <li>Vendor selects military equivalent parts</li> <li>Vendor selects prescreened parts</li> <li>Vendor screens/tests in-house</li> </ul>
Unit quality	• Vendor burns-in all units at higher temps
Part derating	Vendor has in-house standards
Electrical parameters	<ul> <li>Vendor values exceed needs at temp extremes</li> </ul>
Failure analysis	Vendor has failure tracking program
Protection circuits	<ul> <li>Vendor has built-in voltage and current sensors</li> </ul>
Fault flags	Vendor has built-in failure indicators
Reliability experience	Successful operation in similar environments

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

## **Topic D9: Part Failure Modes and Mechanisms**

To properly apply electronic parts in complex and high density equipment designs, the engineer needs to know what factors are significant. With knowledge about the failure modes, mechanisms, and frequency of occurrence design changes can be instituted to eliminate or degrade the accelerating factors thereby increasing the equipment reliability. Table D9-1 presents these factors for a representative group of electronic components. For further information on part construction and operation, consult MIL-HDBK-978B, "NASA Parts Application Handbook," or MIL-HDBK-338, "Electronic Reliability Design Handbook."

## Topic D10: Fiber Optic Design Criteria

Fiber optics are relatively new when compared with most electronic devices. With the increased use of fiber optics comes the need to address fiber optic reliability so that preventive design measures can be instituted. This section will present specific failure modes/mechanisms and their causes and prevention to aid designers/planners in establishing a reliable system. Tables D10-1 thru D10-3 depict those failure modes/mechanisms associated with Transmitters, Receivers and Fiber & Cable. Table D10-4 presents reliability figures of merit with an 80% confidence bound except connectors.

### Table D10-1: Common Failure Mechanisms (Transmitters)

Mode	Causes	Prevention
Facet Damage	Pulse width & optical power density	Apply anti-reflection coat to facets
Laser Wear-Out	Photo-Oxidation, contact degradation & crystal growth defects	Coat facets, reduce temperature & current density & use high quality materials
Laser Instability	Reflection of laser output power	Apply antireflection coat, defocus the graded index coupling element
Shorted Outputs	Whisker formation	Anticipate system lifetime & temperature solder tolerances
Dark Line Defects	Non-Radiating centers	Material selection & quality control

### Table D10-2: Common Failure Mechanisms (Receivers)

Mode	Causes	Prevention
Open Circuit	Fracture of lead-bond plated contacts	Use evaporated contacts
Short or Open Circuit	Short or Open Circuit Electro-Chemical oxidation, humidity	
Positive Intrinsic Negative (PIN) Dark Current	Accumulation of mobile ions	InGaAs or In layer grown on active region & reduce the temperature
Avalanche Photo Diode (APD) Dark Current	Thermal deterioration of the metal contact	Select an APD at 1.3µm & reduce the temperature

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

73

Mode	Causes	Prevention
Cable Open Circuit Fracture	Stress corrosion or fatigue due to microcracks	Residual or threshold tension less than 33% of the rated proof tested tensile strength
Cable Intermittent	Hydrogen migrates into the core of the fiber	Design cables with materials that do not generate hydrogen
Cable Open Circuit Breakage	Temperature cycling, ultraviolet exposure, water & fluid immersion	Design a jacket that can prevent shrinking, cracking, swelling or splitting
Cable Opaque Circuit Inoperative	Radiation	Design to be nuclear radiation hardened

## Table D10-3: Common Failure Mechanisms (Fiber & Cable)

### Table D10-4: Fiber Optic Component Failure Rates

Component Type	Failure Rate (10 <sup>-6</sup> Hrs.)	MTBF (Hrs.)
Fiber	4.35 - 5.26	210,000

### Insight

Reliability and maintainability analyses are a necessary part of most development programs. They provide a means of determining how well the design is progressing towards meeting the program's goals and requirements. They also provide means of evaluating the impact of important design decisions such as cooling approaches, classes of part quality being used, and areas of fault tolerance. In order for the government to receive the outputs of contractor performed analyses, appropriate contract deliverable data items must be required.

## Topic A5: Reliability Analysis Checklist

Major Concerns	Comments
<b>Models</b> Are all functional elements included in the reliability block diagrams/model?	System design drawings/diagrams must be reviewed to be sure that the reliability model/diagram agrees with the hardware.
Are all modes of operation considered in the math model?	Duty cycles, alternate paths, degraded conditions and redundant units must be defined and modeled.
Do the math model results show that the design achieves the reliability requirement?	Unit failure rates and redundancy equations are used from the detailed part predictions in the system math model.
Allocation Are system reliability requirements allocated (subdivided) to useful levels?	Useful levels are defined as: equipment for subcontractors, assemblies for subcontractors, circuit boards for designers.
Does the allocation process consider complexity, design flexibility and safety margins?	Conservative values are needed to prevent reallocation at every design change.
<b>Prediction</b> Does the sum of the parts equal the value of the module or unit?	Many predictions conveniently neglect to include all the parts producing optimistic results (check for solder connections, connectors, circuit boards).
Are the environmental conditions and part quality representative of the requirements?	Optimistic quality levels and favorable environmental conditions are often assumed causing optimistic results.
Are the circuit and part temperatures defined and do they represent the design?	Temperature is the biggest driver of part failure rates; low temperature assumptions will cause optimistic results.
Are equipment, assembly, subassembly and part reliability drivers identified?	Identification is needed so that corrective actions for reliability improvement can be considered.
Are part failure rates from acceptable sources (i.e., MIL-HDBK-217)?	Use of generic failure rates require submission of backup data to provide credence in the values.
Is the level of detail for the part failure rate models sufficient to reconstruct the result?	Each component type should be sampled and failure rates completely reconstructed for accuracy.
Are critical components such as VHSIC, Monolithic Microwave Integrated Circuits (MMIC), Application Specific Integrated Circuits (ASIC) or Hybrids highlighted?	Prediction methods for advanced parts should be carefully evaluated for impact on the module and system.

## Topic A6: Use of Existing Reliability Data

System development programs often make use of existing equipment (or assembly) designs, or designs adapted to a particular application. Sometimes, lack of detailed design information prevents direct prediction of the reliability of these items making use of available field and/or test failure data the only practical way to estimate their reliability. If this situation exists, the following table summarizes the information that is desired.

## Table A6-1: Use of Existing Reliability Data

Information Required	Equipment Field Data	Equipment Test Data	Piece Part Data
Data collection time period	V	V	V
Data collection time period	X	Х	Х
Number of operating hours per equipment	Х	Х	
Total number of part hours			Х
Total number of observed maintenance actions	Х		
Number of "no defect found" maintenance actions	Х		
Number of induced maintenance actions	Х		
Number of "hard failure" maintenance actions	х		
Number of observed failures		Х	х
Number of relevant failures		Х	Х
Number of nonrelevant failures		Х	Х
Failure definition		Х	Х
Number of equipment or parts to which data pertains	х	Х	х
Similarity of equipment of interest to equipment for which data is available	х	Х	
Environmental stress associated with data	х	Х	х
Type of testing		Х	
Field data source	х

## Topic A7: Maintainability/Testability Analysis Checklist

Major Concerns	Comments
Are the maintainability/testability prediction techniques and data used clearly described?	
Is there a clear description of the maintenance concept and all ground rule assumptions?	Repair level, LRU/module definition, spares availability assumptions, test equipment availability assumptions, tools availability assumptions, personnel assumptions, environmental conditions.
Are worksheets provided which show how LRU repair times were arrived at?	The breakout of repair time should include: fault isolation, disassembly, interchange, reassembly and checkout.
Are step-by-step repair descriptions provided to back up repair time estimates?	
Are fault isolation time estimates realistic?	Overestimating BIT/FIT capability is the primary cause of optimistic repair time estimates.
Are fault isolation ambiguity levels considered in the analysis?	
Can repair times be reconstructed from the worksheets and is addition, subtraction, multiplication and division correct?	Checking is mundane but often results in errors and inconsistencies being found.
Are preventive maintenance tasks described?	This includes frequency, maintenance time and detailed task description.
Is all the equipment included in the prediction?	
Has the best procedure been selected to provide estimates for the testability attributes?	Because of the number of variables which effect testability and the number of different procedures available to effect analyses, there must be rationale and logic provided to explain why the particular approach was taken.
Are the numerical values of the testability attributes within specified tolerances?	
Does the test equipment, both hardware and software, meet all design requirements.	All test points should be accessible.
Are the simulation and emulation procedure to be used to simulate/emulate units of the system, for diagnostics development, reasonable and practical?

## Topic A8: FMECA Analysis Checklist

Major Concerns	Comments
Is a system definition/description provided compatible with the system specification?	
<ul> <li>Are ground rules clearly stated?</li> </ul>	<ul> <li>These include approach, failure definition, acceptable degradation limits, level of analysis, clear description of failure causes, etc.</li> </ul>
<ul> <li>Are block diagrams provided showing functional dependencies at all equipment indenture levels?</li> </ul>	• This diagram should graphically show what items (parts, circuit cards, sub- systems, etc.) are required for the successful operation of the next higher assembly.
• Does the failure effect analysis start at the lowest hardware level and systematically work to higher indenture levels?	• The analysis should start at the lowest level specified in the SOW (e.g. part, circuit card, subsystem, etc.)
<ul> <li>Are failure mode data sources fully described?</li> </ul>	<ul> <li>Specifically identify data sources per MIL-HDBK-338, Para 7.3.2, include relevant data from similar systems.</li> </ul>
• Are detailed FMECA worksheets provided? Do the worksheets clearly track from lower to higher hardware levels? Do the worksheets clearly correspond to the block diagrams? Do the worksheets provide an adequate scope of analysis?	• Worksheets should provide an item name indenture code, item function, list of item failure modes, effect on next higher assembly and system for each failure mode, and a criticality ranking. In addition, worksheets should account for multiple failure indenture levels for Class I and Class II failures.
<ul> <li>Are failure severity classes provided? Are specific failure definitions established?</li> </ul>	<ul> <li>Typical classes are:</li> <li>Catastrophic (life/death)</li> <li>Critical (mission loss)</li> <li>Marginal (mission degradation)</li> <li>Minor (maintenance/repair)</li> </ul>
Are results timely?	<ul> <li>Analysis must be performed "during" the design phase not after the fact.</li> </ul>
<ul> <li>Are results clearly summarized and are clean comprehensive recommendations provided?</li> </ul>	<ul> <li>Actions for risk reduction of single point failures, critical items, areas needing BIT/FIT, etc.</li> </ul>

• Are the results being submitted (shared) to enhance other program decisions?

• BIT design, critical parts, reliability prediction, derating, fault tolerance.

PRO Qu Quanterion Automated Reliability Toolkit

## Topic A9: Redundancy Equations

Many military electronic systems readiness and availability requirements exceed the level of reliability to which a serial chain system can be practically designed. Use of high quality parts, a sound thermal design and extensive stress derating may not be enough. Fault tolerance, or the ability of a system design to tolerate a failure or degradation without system failure, is required. The most common form of fault tolerance is redundancy where additional, usually identical, units are added to a system in parallel with the other units. Because this situation is very common, the reliability equations for common redundancy situations are included below.

The following represents a sample list of specific redundancy relationships which define failure rate as a function of the specific type of redundancy employed. For a comprehensive treatment of redundancy concepts and the reliability improvements achievable through their applications see RADC-TR-77-287, "A Redundancy Notebook."

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

89

### Table A9-1: Redundancy Equation Approximations Summary

Redundan	cy Equations	
With Repair	Without Repair	
All units are active on-line with equal unit failure rates. (n-q) out of n required for success.		

Equation 4

Equation 5

 $\lambda_{(n-q)/n} = \frac{\lambda}{n}$ i=n-q

 $\lambda_{1/2} = \frac{\lambda_A^2 \lambda_B + \lambda_A \lambda_B^2}{\lambda_A^2 + \lambda_B^2 + \lambda_A \lambda_B}$ 

#### Equation 1

$$\lambda_{(n-q)/n} = \frac{n! (\lambda)^{q+1}}{(n-q-1)!(\mu)^{q}}$$

Two active on-line units with different failure and repair rates. One of two required for success.

#### **Equation 2**

$$\lambda_{1/2} = \frac{\lambda_A \lambda_B \left[ (\mu_A + \mu_B) + (\lambda_A + \lambda_B) \right]}{(\mu_A)(\mu_B) + (\mu_A + \mu_B)(\lambda_A + \lambda_B)}$$

$$\lambda_{n/n+1} = \frac{n[n\lambda + (1-P)\mu]\lambda}{\mu + n(P+1)\lambda}$$

#### Key:

 $\lambda_{X/Y}$  is the effective failure rate of the redundant configuration where x of y units are required for success

- n = number of active on-line units. n! is n factorial (e.g., 5!=5x4x3x2x1=120, 1!=1,0!=1)
- $\lambda$  = failure rate of an individual on-line unit (failures/hour)
- q = number of on-line active units which are allowed to fail without system failure
- $\mu$  = repair rate ( $\mu$ =1/M<sub>Ct</sub>, where M<sub>Ct</sub> is the mean corrective maintenance time in hours)
- P = probability switching mechanism will operate properly when needed (P=1 with perfect switching)

#### Notes:

- 1. Assumes all units are functional at the start
- 2. The approximations represent time to first failure
- 3. **CAUTION:** Redundancy equations for repairable systems should not be applied if delayed maintenance is used.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

90

Copies of this Toolkit may be downloaded free from <u>quanterion.com</u>. Many of the tools in this Toolkit are implemented in the "Quanterion Automated Reliability Toolkit" (QuART), which can be download a free from <u>quanterion.com</u>.

Equation 6

$$\lambda_{n/n+1} = \frac{n\lambda}{P+1}$$

**Example 1:** A system has five active units, each with a failure rate of 220 f/10<sup>6</sup> hours, and only three are required for successful operation. If one unit fails, it takes an average of three hours to repair it to an active state. What is the effective failure rate of this configuration?

**Solution:** Substituting the following values into Equation 1:

n = 5  
q = 2  

$$\mu$$
 = 1/3  
 $\lambda_{(5-2)/5} = \lambda_{3/5}$   
 $\lambda_{3/5} = \frac{5!(220 \cdot 10^{-6})^3}{(5-2-1)!(1/3)^2} = 5.75 \cdot 10^{-9}$  f/hour  
 $\lambda_{3/5} = .00575$  f/10<sup>6</sup> hours

**Example 2:** A ground radar system has a 2 level weather channel with a failure rate of 50 f/10<sup>6</sup> hours and a 6 level weather channel with a failure rate of 180 f/10<sup>6</sup> hours. Although the 6 level channel provides more comprehensive coverage, the operation of either channel will result in acceptable system operation. What is the effective failure rate of the two channels if one of two are required and the M<sub>ct</sub> is 1 hour?

**Solution:** Substituting the following values into Equation 2:

$$\begin{split} \lambda_{A} &= 50 \cdot 10^{-6} \\ \lambda_{B} &= 180 \cdot 10^{-6} \\ \mu_{A} &= \mu_{B} = 1/M_{ct} = 1 \\ \lambda_{1/2} &= \frac{(50 \cdot 10^{-6})(180 \cdot 10^{-6})[(1+1) + (50 \cdot 10^{-6} + 180 \cdot 10^{-6})]}{(1)(1) + (1+1)(50 \cdot 10^{-6} + 180 \cdot 10^{-6})} = 1.8 \cdot 10^{-8} \text{ f/hour} \end{split}$$

 $\lambda_{1/2}$  = .018 f/10<sup>6</sup> hours

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

91

## Topic A10: Parts Count Reliability Prediction

A standard technique for predicting reliability when detailed design data such as part stress levels is not yet available is the parts count reliability prediction technique. The technique has a "built-in" assumption of average stress levels which allows prediction in the conceptual stage or source selection stage by estimation of the part types and quantities. This section contains a summary of the MIL-HDBK-217F, Notice 1 technique for eleven of the most common operational environments:

- G<sub>B</sub> Ground Benign
- G<sub>F</sub> Ground Fixed
- G<sub>M</sub> Ground Mobile
- N<sub>S</sub> Naval Sheltered
- N<sub>U</sub> Naval Unsheltered
- AIC Airborne Inhabited Cargo
- A<sub>IF</sub> Airborne Inhabited Fighter
- A<sub>UC</sub> Airborne Uninhabited Cargo
- A<sub>UF</sub> Airborne Uninhabited Fighter
- A<sub>RW</sub> Helicopter (Both Internal and External Equipment)

S<sub>F</sub> Space Flight

Assuming a series reliability model, the equipment failure rate can be expressed as:

$$\lambda_{EQUIP} = \sum_{i=1}^{n} (N_i)(\lambda_{gi})(\pi_{Qi})$$

where

$\lambda_{EQUIP}$	=	total equipment failure rate (failures/10 <sup>6</sup> hrs)
<sup>λ</sup> gi	=	generic failure rate for the ith generic part type (failures/10 <sup>6</sup> hrs)
$\pi_{Qi}$	=	quality factor for the ith generic part type
N <sub>i</sub>	=	quantity of the ith generic part type
n	=	number of different generic part types

Non</li> </ul>	$F_Q = 2 + \frac{87}{\sum Po \text{ int } Valuations}$ TIPOTIPIATE $\Phi OP \Pi \Lambda A \Sigma TIX \Pi APT\Sigma$ Int valuation only assigned if used independent of Groups 1, 2 or 3. Int valuation only assigned if used independent of Groups 1 or 2. Intervaluencing of tests within groups 1, 2 and 3 must be followed. refers to the MIL-STD-883 Test Method. Intermetic parts should be used only in controlled environments (i.e., of perature/humidity controlled environments).	GB and other
EXAMPLE		
	erforms Group 1 test and Class B burn-in: $\pi_Q = 2 + \frac{87}{50+30} = 3.1$	
	erforms internal visual test, seal test and final electrical test: $\pi = 2$ -	+ = 5.5
Other Con	nmercial or Unknown Screening Levels $\pi_Q = 10$	I

## Microcircuit Quality Factors (cont'd): $\pi_{\mathbf{Q}}$ Calculation for Custom Screening Programs

# Table A10-7: $\pi_{\mathbf{Q}}$ Factor for Use with Inductive, Electromechanical and Miscellaneous Parts

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

# Topic A11: Reliability Adjustment Factors

"What if" questions are often asked regarding reliability figures of merit. For a rapid translation, tables for different quality levels, various environments and temperatures are presented to make estimates of the effects of the various changes. The data base for these tables is a grouping of approximately 18000 parts from a number of equipment reliability predictions performed in-house on military contracts. The ratios were developed using this data base and MIL-HDBK-217F algorithms. The relative percentages of the part data base are shown as follows:

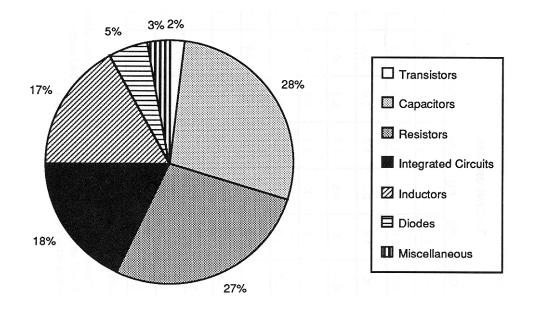

Table A11-1: Part Quality Factors	(Multiply MTBF by)
-----------------------------------	--------------------

			To Quality	Class	
		Space	Full Military	Ruggedized	Commercial
	Space	Х	0.8	0.5	0.2
From	Full Military	1.3	Х	0.6	0.2
Quality	Ruggedized	2.1	1.6	Х	0.4
Class	Commercial	5.3	4.1	2.5	Х
	IC	Class S	Class B	Class B-1	Class D
	Semiconductor	JANTXV	JANTX	JAN	NONMIL
	Passive Part	ER(S)	ER(R)	ER(M)	NONMIL

CAUTION: Do not apply to Mean-Time-Between-Critical-Failure (MTBCF).

# Topic A12: Surface Mount Technology (SMT) Assessment Model

The SMT Model was developed to assess the life integrity of leadless and leaded devices. It provides a relative measure of circuit card wearout due to thermal cycling fatigue failure of the "weakest link" SMT device. An analysis should be performed on all circuit board SMT components. The component with the largest failure rate value (weakest link) is assessed as the overall board failure rate due to SMT. The model assumes the board is completely renewed upon failure of the weakest link and the results do not consider solder or lead manufacturing defects. This model is based on the techniques developed in the Rome Laboratory technical report RL-TR-92-197, "Reliability Assessment of Critical Electronic Components."

 $\lambda_{SMT}$  = Average failure rate over the expected equipment life cycle due to surface mount device wearout. This failure rate contribution to the system is for the Surface Mount Device on each board exhibiting the highest **absolute** value of the strain range:

$$\left[\left(\alpha_{s} \Delta T - \alpha_{CC} \left(\Delta T + T_{RISE}\right)\right) \times 10^{-6}\right]$$

$$\lambda_{\text{SMT}} = \frac{\text{ECF}}{\alpha_{\text{SMT}}}$$

ECF = Effective cumulative number of failures over the Weibull characteristic life.

LC = Design life cycle of the equipment in which the circuit board is operating.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

108

 $\alpha_{SMT}$  = The Weibull characteristic life.  $\alpha_{SMT}$  is a function of device and substrate material, the manufacturing methods, and the application environment used.

$$\alpha_{\text{SMT}} = \frac{N_{\text{f}}}{CR}$$

where:

CR = Temperature cycling rate in cycles per calendar hour

N<sub>f</sub> = Average number of thermal cycles to failure

N<sub>f</sub> = 3.5 
$$\left(\frac{d}{.65h} \left| (\alpha_s \Delta T - \alpha_{cc} (\Delta T + T_{RISE})) \right| x 10^{-6} \right)^{-2.26} (\pi_{LC})$$

where:

d

=	Distance from center of device to the furthest solder joint in
	mils (thousandths of an inch)

- h = Solder joint height in mils for leadless devices. Use h = 8 for all leaded configurations.
- $\alpha_S$  = Circuit board substrate thermal coefficient of expansion (TCE)
- $\Delta_{T}$  = Use environment temperature difference
- $\alpha_{CC}$  = Package material thermal coefficient of expansion (TCE)
- $T_{RISE} = Temperature rise due to power dissipation (Pd)$   $Pd = \theta_{JC}P \qquad \qquad \theta_{JC} = Thermal resistance ^{\prime}Watt$  P = Watts

 $\pi_{LC}$  = Lead configuration factor

### Table A12-6: $\alpha_{S}$ - TCE Substrate Values

**Example:** A large plastic encapsulated leadless chip carrier is mounted on a epoxy-glass printed wiring assembly. The design considerations are: a square package is 1480 mils on a side, solder height is 5 mils, power dissipation is .5 watts, thermal resistance is 20°C/watt, the design life is 20 years and environment is military ground application. The failure rate developed is the impact of SMT for a single circuit board and accounts for **all** SMT devices on this board. This failure rate is added to the sum of all of the component failure rates on the circuit board.

# Topic A13: Finite Element Analysis

# Background

Finite Element Analysis (FEA) is a computer simulation technique that can predict the material response or behavior of a modeled device. These analyses can provide material stresses and temperatures throughout modeled devices by simulating thermal or dynamic loading situations. FEA can be used to assess mechanical failure mechanisms such as fatigue, rupture, creep, and buckling.

## When to Apply

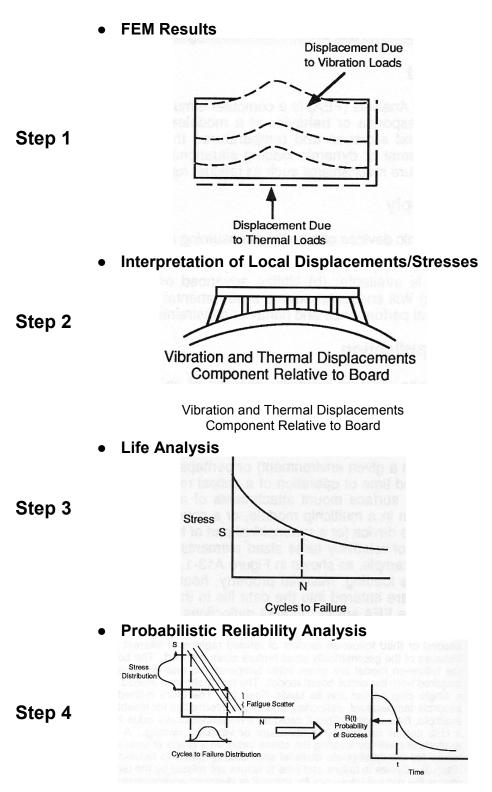

FEA of electronic devices can be time consuming and analysis candidates must be carefully selected. Selection criteria includes devices, components, or design concepts which: (a) Are unproven and for which little or no prior experience or test information is available; (b) Utilize advanced or unique packaging or design concepts; (c) Will encounter severe environmental loads; (d) Have critical thermal or mechanical performance and behavior constraints.

# **Typical Application**

A typical finite element reliability analysis of an electronic device would be an assessment of the life (i.e. number of thermal or vibration cycles to failure or hours of operation in a given environment) or perhaps the probability of a fatigue failure after a required time of operation of a critical region or location within the device. Examples are surface mount attachments of a chip carrier to a circuit board, a critical location in a multichip module, or a source via in a transistor microcircuit. First, the entire device (or a symmetrical part of the entire device) is modeled with a coarse mesh of relatively large sized elements such as 3-dimensional brick elements. For example, as shown in Figure A13-1, an entire circuit board is analyzed (Step 1). The loading, material property, heat sink temperature, and structural support data are entered into the data file in the proper format and sequence as required by the FEA solver. Output deflections and material stresses for all node point locations on the model are then acquired. For microelectronic devices, second or third follow-on models of refined regions of interest may be required because of the geometrically small feature sizes involved. The boundary nodes for the follow-on model are given initial temperatures and displacements that were acquired from the circuit board model. The figure shows a refined region containing a single chip carrier and its leads (Step 2). The more refined models provide accurate temperature, deflection, and stress information for reliability analyses. For example, the results of Step 2 could be a maximum stress value in a corner lead of a chip carrier caused by temperature or vibration cycling. Α deterministic life analysis is made by locating the stress value on a graph of stress versus cycles to failure for the appropriate material and reading cycles to failures on the abscissa (Step 3). Cycles to failure and time to failure are related by the temperature cycling rate or the natural frequency for thermal or dynamic environments, respectively. A distribution of stress coupled with a distribution of strength (i.e. scatter in fatigue data) will result in a probability distribution function and a cumulative distribution function of time to failure (Step 4).

# **Topic A14: Common Thermal Analysis Procedures**

The following graphs and associated examples provide a guide for performing basic integrated circuit junction temperature calculations for three of the most common types of cooling designs: impingement, cold wall, and flow through modules. This procedure is intended to provide the Reliability Engineer with a simple means of calculating approximate junction temperatures and for performing a quick check of more detailed thermal analysis calculations.

## **Card-Mounted, Flow-through Modules**

#### Notes:

- 1. Module dissipation uniformly distributed and applied on both sides.
- 2. The part junction temperature is obtained as follows:

 $T_J = T_A + \Delta T_{BA} + (\theta_{JC} + \theta_{CB}) Q_P$ where

T<sub>.1</sub> is the junction temperature

T<sub>A</sub> is the cooling air inlet

ΔT<sub>RA</sub> is the weighted average heat-exchanger-to-cooling-air inlet temperature difference (See Note 4)

 $\theta_{\text{IC}}$  is the junction-to-case thermal resistance in °C/W

 $\boldsymbol{\theta}_{CB}$  is the thermal resistance between the case and the heat exchanger in °C/W

 $Q_{\mathbf{D}}$  is the part power dissipation in watts

- 3. All temperatures are in °C
- 4. Weighted average temperature difference is the value at a location two thirds of the distance from the inlet to the outlet, as shown in sketch. Experience has shown that the temperature at this location approximates the average board temperature.

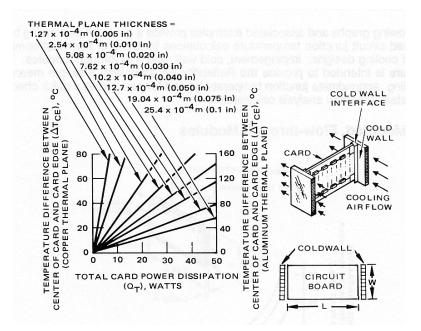

## Figure A14-1: Estimated Temperature of Card-mounted Parts Using Forced-air-cooled Flow-through Modules

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

115

## Card-Mounted, Air-Cooled Coldwalls

#### Notes:

- 1.  $\Delta T_{CF}$  from curve is for L/W = 2; for other L/W ratios, multiply  $\Delta T_{CF}$  from curve by 0.5 L/W
- 2. The junction temperature is obtained as follows:

$$T_J = T_A + \frac{0.03 Q_T}{m_a} + \Delta T_{CE} + Q_T (0.0761/W + 0.25) + Q_P (\theta_{JC} + \theta_{CB})$$

where

3

- $\begin{array}{l} T_{J} \text{ is the junction temperature} \\ T_{A} \text{ is the air inlet temperature} \\ Q_{T} \text{ is the total card power dissipation in watts} \\ Q_{P} \text{ is the part power dissipation in watts} \\ m_{a} \text{ is the airflow rate in Kg/Min} \\ \Delta T_{CE} \text{ is the temperature difference between center of card and card edge} \\ W \text{ is the card width in meters} \\ \theta_{JC} \text{ is the junction-to-case thermal resistance in °C/W} \\ \theta_{CB} \text{ is the case-to-mounting surface thermal resistance in °C/W} \\ \text{All temperatures are in °C} \end{array}$
- 4. The card edge to card guide interface thermal resistance is 0.0761 °C/W per meter of card width
- 5. The coldwall convective thermal resistance is 0.25°C/W

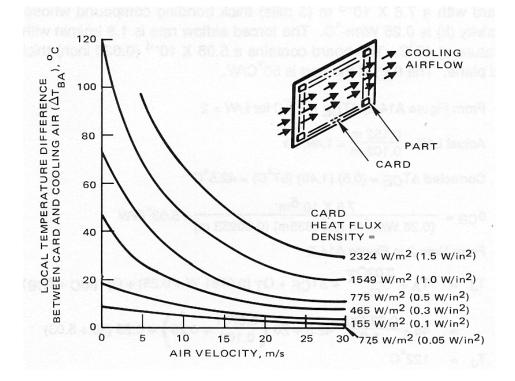

### Figure A14-2: Estimated Temperature of Card-mounted Parts Using Forced-air Cooled Coldwalls

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

116

## Air Impingement, Card-Mounted

#### Notes:

1. The part junction temperature is obtained as follows:

 $T_{J} = T_{A} + \Delta T_{BA} + (\theta_{JC} + \theta_{CB}) Q_{P}$ 

where

- T<sub>J</sub> is the junction temperature
- $T_A$  is the local cooling air temperature

 $\Delta T_{BA}$  is the local card-to-air temperature difference

 $\theta_{JC}$  is the junction-to-case thermal resistance in °C/W

- $\theta_{CB}$  is the case-to-mounting-surface thermal resistance in °C/W
- $\mathsf{Q}_{\mathsf{P}}$  is the part power dissipation in watts
- 2. All temperatures are in °C
- 3. Assumes all the heat is uniformly distributed over both sides of the board
- 4. Assumes no air temperature rise (add any rise in air temperature to the result)

## Figure A14-3: Estimated Temperature of Card-mounted Parts Using Forced-air Impingement Cooling at Sea Level

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

117

#### Example 1: Card Mounted, Air Cooled Coldwalls

Estimate the junction temperature of a 0.25-W microcircuit mounted at the center of a coldwall-cooled circuit board, 0.152 X 0.102 m, with a total power dissipation of 20 W. The part, which has a mounting base of 0.00635 X 0.00953 m, is attached to the board with a 7.6 X  $10^{-5}$  m (3 mils) thick bonding compound whose thermal conductivity (k) is 0.25 W/m-°C. The forced airflow rate is 1.8 kg/min with an inlet temperature of 45°C. The board contains a 5.08 X  $10^{-4}$  (0.020 inch) thick copper thermal plane. The  $\theta_{\rm JC}$  of the part is 50°C/W.

1. From Figure A14-2,  $\Delta T_{CE} = 57^{\circ}C$  for L/W = 2

Actual L/W =  $\frac{0.152 \text{ m}}{0.102 \text{ m}}$  = 1.49, so

Corrected  $\Delta T_{CE} = (0.5) (1.49) (57^{\circ}C) = 42.5^{\circ}C$ 

- 2.  $\theta_{\text{CB}} = \frac{7.6 \times 10^{-5} \text{m}}{(0.25 \text{ W/m}^{\circ} \text{C}) (0.00635 \text{m}) (0.00953 \text{ m})} = 5.03^{\circ} \text{C/W}$
- 3. From Note 2 in Figure A14-2

$$T_{J} = T_{A} + \frac{0.03Q_{T}}{m_{a}} + \Delta T_{CE} + Q_{T} (0.0761 \text{ W} + 0.25) + Q_{P} (\theta_{JC} + \theta_{CB})$$
$$= 45 + \frac{0.03 (20)}{1.8} 42.5 + 20 \left(\frac{0.0761}{0.102} + 0.25\right) + 0.25 (50 + 5.03)$$
$$T_{J} = 122^{\circ}C$$

#### Example 2: Air Impingement, Card Mounted Cooling

Estimate the junction temperature of a part dissipating 0.25 W and mounted on a circuit board cooled by impingement with ambient air at 40 °C and a velocity of 15 m/s. The circuit board, whose dimensions are 0.102 X 0.152 m, has a total power dissipation of 20 W. The part, whose mounting base is 0.00635 X 0.00953 m, is attached to the board with a 7.61 X  $10^{-5}$  m (3 mils) thick bonding compound whose thermal conductivity (k) is 0.25 W/m-°C. The junction-to-case thermal resistance ( $\theta_{\rm IC}$ ) of the part is 50 °C/W.

1. Compute the card heat flux density (see Note 3 in Figure A14-3):

 $\frac{20 \text{ W}}{2 (0.102 \text{ m}) (0.152 \text{ m})} = 645 \text{ W/m}^2$ 

2. From Figure A14-3:  $\Delta T_{BA} = 17^{\circ}C$ 

3. 
$$\theta_{\text{CB}} = \frac{7.61 \times 10^{-5} \text{ m}}{(0.25 \text{W/m}^{\circ} \text{C}) (0.00635 \text{ m}) (0.00953 \text{ m})} = 5.03^{\circ} \text{C/W}$$

- 4. From Note 1 in Figure A14-3
  - $T_J = T_A + \Delta T_{BA} + (\theta_{JC} + \theta_{CB}) Q_P = 40 + 17 + (50 + 5.03) 0.25$  $T_J = 71^{\circ}C$

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

118

# Topic A15: Sneak Circuit Analysis

Electronics that operate within their specifications are still vulnerable to critical failures. Hidden within the complexity of electronic designs are conditions that slip past standard stress tests. These conditions are known as sneak circuits.

## Definitions

- **Sneak Circuit:** A condition which causes the occurrence of an unwanted function or inhibits a desired function even though all components function properly.
- **Sneak Paths:** Unintended electrical paths within a circuit and its external interfaces.
- **Sneak Timing:** Unexpected interruption or enabling of a signal due to switch circuit timing problems.
- Sneak Indications: Undesired activation or de-activation of an indicator.
- Sneak Labels: Incorrect or ambiguous labeling of a switch.
- **Sneak Clue:** Design rule applied to a circuit pattern to identify design inconsistencies.

### **Cause of Sneaks**

- Complex designs with many interfaces
- Flaws unknowingly designed into equipment
- Switching and timing requirements
- Incomplete analyses and test

## Why Do Sneak Analysis?

- Method for detecting hidden failures
- Verification of interface switching and timing requirements
- Improves system/unit reliability

### Where are Sneak Circuits?

- Electrical power systems
- Switching circuits
- Distribution and control systems
- Software control functions
- Interface configurations

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

119

Clue	Sneak	Impact
Fanout Exceeded	Design Concern	Unpredictable Outputs
Unterminated CMOS Input	Design Concern	Device Damage
Large Time Constant	Sneak Timing	Unpredictable Switching Times
Uncommitted Open Collector Output	Design Concern	False Unstable Logic

## **Table A15-1: Typical Clue Statements**

## Performing Sneak Analysis

- **Time to complete analysis:** An average Sneak Circuit Analysis (SCA) is a lengthy process that requires several months to complete. Redrawing the electronics of a system into hundreds of topographical patterns and checking each one against a multitude of sneak clues is a time consuming task.
- **Cost of analysis:** SCA specialists will be required due to the need for proprietary sneak clues. Their cost of analysis is based on part count and design complexity. Outside specialists, not familiar with the design, will require extra time and money to complete a detailed analysis of the functions and operation of a design. This learning curve cost is in addition to the cost of analysis.
- Availability of results: A manual SCA requires preproduction level drawings to prevent late design changes from inserting new sneaks into the system after performing the analysis. Extra time must be available to review the results or taking the necessary corrective action will require hardware rework, recall, or redesign rather than drawing changes.

### For More Information

To perform a manual analysis, many independent contractors are available for contracts. If in-house work is contemplated, RADC-TR-89-223, "Sneak Circuit Analysis for the Common Man," is recommended as a guide. Automated tools are available including the Rome Laboratory prototype called SCAT (Sneak Circuit Analysis Tool). A new Rome Laboratory tool, Sneak Circuit Analysis Rome Laboratory Engineering Tool (SCARLET), is in development for future use.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

120

## Example: Subsystem Sneak Circuit Reverse Current Operation

Figure A15-1a shows the original circuit which was designed to prevent routine opening of the cargo door unless the aircraft was on the ground with the gear down and locked. The secondary switch permits emergency operation of the door when the gear is not down. Figure A15-1b shows the network tree diagram which indicates the existence of a sneak path. If the emergency and normal door open switches are both closed, the gear will be inadvertently lowered. The solution to the problem is the addition of a diode to prevent reverse current flow as shown in Figure A15-1c.

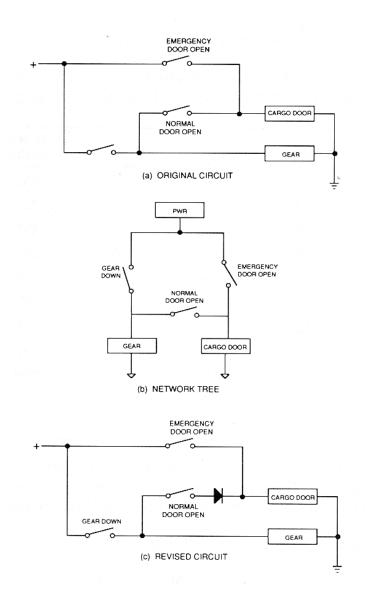

Figure A15-1: Sneak Circuit Example

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

121

# Topic A16: Dormant Analysis

In the past, analysis techniques for determining reliability estimates for dormant or storage conditions relied on rules of thumb such as "the failure rate will be reduced by a ten to one factor" or "the failure rate expected is zero." A more realistic estimate, based on part count failure results, can be calculated by applying the conversion factors shown in Table A16-1. The factors convert active failure rates by part type to passive or dormant conditions for seven scenarios. For example, to convert the reliability of an active airborne receiver to a captive carry dormant condition, determine the number of components by type, then multiply each by the respective active failure rate obtained from handbook data, field data, or vendor estimates. The total active failure rate for each type is converted using the conversion factors of Table A16-1. The dormant estimate of reliability for the receiver is determined by summing the part results.

## Example: Aircraft Receiver Airborne Active Failure Rate to Captive Carry Passive Failure Rate

				Conversion

# Table A16-1: Dormant Conversion Factors(Multiply Active Failure Rate by)

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

# Topic A17: Software Reliability Prediction and Growth

Software failures arise from a population of software faults. A software fault (often called a "bug") is a missing, extra, or defective code that has caused or can potentially cause a failure. Every time a fault is traversed during execution, a failure does not necessarily ensue; it depends on the machine state (values of intermediate variables). The failure rate of a piece of software is a function of the number and location of faults in the code, how fast the program is being executed, and the operational profile. While most repair activity is imperfect, the hoped-for and generally observed result is that the times between failures tend to grow longer and longer as the process of testing and fault correction goes on. A software reliability growth model mathematically summarizes a set of assumptions about the phenomenon of software failure. The model provides a general form for the failure rate as a function of time and contains parameters that are determined either by prediction or estimation.

The following software reliability prediction and growth models are extracted from Rome Laboratory Technical Report RL-TR-92-15, "Reliability Techniques For Combined Hardware and Software Systems." These models can be used to estimate the reliability of initially released software along with the reliability improvement which can be expected during debugging.

## Initial Software Failure Rate

$$\lambda_0 = \frac{r_i K W_0}{I}$$
 failures per CPU second

where

ri	=	host processor speed (instructions/sec)	
----	---	---	--

- K = fault exposure ratio which is a function of program data dependency and structure (default =  $4.2 \times 10^{-7}$ )
- W<sub>0</sub> = estimate of the total number of faults in the initial program (default = 6 faults/1000 lines of code)
- number of object instructions which is determined by number of source lines of code times the expansion ratio

Programming Language	Expansion Ratio
Assembler	1
Macro Assembler	1.5
С	2.5
COBOL	3
FORTRAN	3
JOVIAL	3
Ada	4.5

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

124

### Software Reliability Growth

$$\lambda(t) = \lambda_0 e^{-[\beta t]}$$

where

λ(t) λ <sub>Ο</sub> t	=	software failure rate at time t (in CPU time) initial software failure rate CPU execution time (seconds)
β	=	decrease in failure rate per failure occurrence
β	=	$B \frac{\lambda_0}{W_0}$
		<ul> <li>B = fault reduction factor (default = .955)</li> <li>W<sub>0</sub> = initial number of faults in the software program per 1,000 lines of code</li> </ul>

**Example 1:** Estimate the initial software failure rate and the failure rate after 40,000 seconds of CPU execution time for a 20,000 line Ada program:

- r<sub>i</sub> = 2 MIPS = 2,000,000 instructions/sec
- $K = 4.2 \times 10^{-7}$
- $W_0$  = (6 faults/1000 lines of code) (20,000 lines of code) = 120 Faults
  - I = (20,000 source lines of code) (4.5) = 90,000 instructions

$$\lambda_0 = \frac{(2,000,000 \text{ inst./sec}) (4.2 \times 10^{-7}) (120 \text{ faults})}{90,000 \text{ inst.}}$$

 $\lambda_0$  = .00112 failures/CPU second

$$\beta$$
 = B  $\frac{\lambda_0}{W_0}$  = (.955) ( $\frac{.00112 \text{ failures/sec}}{120 \text{ faults}}$ )

- $\beta$  = 8.91 x 10<sup>-6</sup> failures/sec
- $\lambda$  (40,000) = .00112 e<sup>-[</sup> (8.91 x 10<sup>-6</sup> failures/sec) (40,000 sec)]

 $\lambda$  (40,000) = .000784 failures/CPU second

#### Insight

A well tailored reliability and maintainability program contains several forms of testing. Depending on the program constraints, a program should be invoked to mature the designed in reliability as well as to determine whether the contract quantitative reliability and maintainability requirements have been achieved prior to a commitment to production. All forms of testing (Environmental Stress Screening (ESS), Reliability Growth, Reliability Demonstration) must be tailored to fit specific program constraints. Test plans and procedures must be evaluated to ensure proper test implementation. Test participation depends on the program situation but test reports must be carefully evaluated by the government.

# Topic T1: ESS Process

Environmental Stress Screening (ESS) has been the subject of many recent studies. Determination of the optimum screens for a particular product, built by a particular manufacturer, at a given time is an iterative process. Procedures for planning for and controlling the screening process are contained in DOD-HDBK-344 (USAF), "Environmental Stress Screening of Electronic Equipment." The process can be depicted as shown below:

## Figure T1-1: ESS Process

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

129

# Topic T2: ESS Placement

Level of Assembly	Advantages	Disadvantages		
Assembly	<ul> <li>Cost per flaw precipitated is lowest (unpowered screens)</li> </ul>	<ul> <li>Test detection efficiency is relatively low</li> </ul>		
	<ul> <li>Small size permits batch screening</li> </ul>	<ul> <li>Test equipment cost for powered screens is high</li> </ul>		
	<ul> <li>Low thermal mass allows high rates of temperature change</li> </ul>			
	<ul> <li>Temperature range greater than operating range allowable</li> </ul>			
Unit	<ul> <li>Relatively easy to power and monitor performance during screen</li> </ul>	Thermal mass precludes high rates of change or requires costly facilities		
	<ul> <li>Higher test detection efficiency than assembly level</li> </ul>	Cost per flaw significantly higher than assembly level		
	<ul> <li>Assembly interconnections (e.g., wiring backplane) are screened</li> </ul>	Temperature range reduced from assembly level		
System	<ul> <li>All potential sources of flaws are screened</li> </ul>	Difficult and costly to test at temperature extremes		
	Unit interoperability flaws     detected	<ul> <li>Mass precludes use of effective vibration screens or makes use costly</li> </ul>		
	High test detection efficiency	<ul> <li>Cost per flaw is highest</li> </ul>

### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

131

#### Notes:

- 1. All temperature parameters pertain to agreed upon selected sample points inside the unit being screened, not chamber air temperature.
- 2. Rapid transfers of the equipment between one chamber at maximum temperature and another chamber at minimum temperature are acceptable. SRU temperature rates of change may be reduced if equipment damage will occur at 20°C/minute.
- 3. The temperature has stabilized when the temperature of the part of the test item considered to have the longest thermal lag is changing no more than 2°C per hour.
- 4. A minimum of 5 thermal cycles must be completed after the random vibration screen. Random vibration frequently induces incipient failures.
- 5. Shall occur during the low to high temperature excursion of the chamber and during vibration. When operating, equipment shall be at maximum power loading. Power will be OFF on the high to low temperature excursion until stabilized at the low temperature. Power will be turned ON and OFF a minimum of three times at temperature extremes on each cycle.
- 6. Instantaneous go/no-go performance monitoring during the stress screen is essential to identify intermittent failures when power is on.
- 7. Specific level may be tailored to individual hardware specimen based on vibration response survey and operational requirements.
- 8. When random vibration is applied at the equipment level, random vibration is not required at the subassembly level. However, subassemblies purchased as spares are required to undergo the same random vibration required for the equipment level. An "LRU mock-up" or equivalent approach is acceptable.
- 9. One axis will be perpendicular to plane of the circuit board(s)/LRM(s).
- The Air Force or its designated contractor may audit part defective rates at its discretion. The test procedure will include thermal cycling as outlined below. Sample sizes and test requirements are included in the "Stress Screening Military Handbook," DOD-HDBK-344.

Minimum Temperature Range	From - 54°C to + 100°C
Minimum Temperature Rate of Change	The total transfer time from hot-to-cold or cold- to-hot shall not exceed one minute. The working zone recovery time shall be five minutes maximum after introduction of the load from either extreme in accordance with MIL- STD-883D.
Temperature Dwell	Until Stabilization (See Note 3)
Minimum Temperature Cycles	25
Power On/Equipment Monitoring	No
Electrical Testing After Screen	Yes (At high and low temperatures)

# Topic T4: RGT and RQT Application

The Reliability Qualification Test (RQT) is an "accounting task" used to measure the reliability of a fixed design configuration. It has the benefit of holding the contractor accountable some day down the road from his initial design process. As such, he is encouraged to seriously carry out the other design related reliability tasks. The Reliability Growth Test (RGT) is an "engineering task" designed to improve the design reliability. It recognizes that the drawing board design of a complex system cannot be perfect from a reliability point of view and allocates the necessary time to fine tune the design by finding problems and designing them out. Monitoring, tracking and assessing the resulting data gives insight into the efficiency of the process and provides nonreliability persons with a tool for evaluating the development's reliability status and for reallocating resources when necessary. The forms of testing serve very different purposes and complement each other in development of systems and equipments. An RGT is not a substitute for an RQT, or other reliability design tasks.

# Topic T6: Maintainability Demonstration Plan Selection

	Program Constraints				
Test Characteristic	Calendar Time Required	Number of Equipments Available	Test Facility Limitations	Level of Maintainabilit y Required	Desired Confidence in Results
Fixed sample size or sequential type tests	Much less than that required for reliability demo. Time required is proportional to sample size number. Sample size may vary depending on program.	No effect on sample size number.		No effect on sample size number.	Fixed sample size test gives demonstrated maintainability to desired confidence. Sequential is test of hypothesis.
Test plan risks (consumer and producer) (1 - consumer risk = confidence) Risks can be tailored to program	Lower producer and consumer risks require larger sample sizes than higher risks.		Must have ability to simulate operational maintenance environment, scenario, skills, levels available.	No effect on sample size number.	Higher confidence levels require more samples than lower confidence levels.

Note: Demonstration facility must have capacity for insertion of simulated faults.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

136

# Topic T7: Testability Demonstration Plan Selection

	Program Constraints							
Test Characteristic	Calendar Time Required	Number of Equipments Available	Test Facility Limitations	Desired Confidence in Results				
Fixed sample size type tests	Calendar time much less than that required for reliability demonstration. Time required is proportional to sample size. May vary depending on program.	No effect on sample size number.	Same as that required for maintainability demonstration.	Provides for producer's risks of 10%. Provides consumer assurance that designs with significant deviations from specified values will be rejected.				
Preset Risks (consumer and producer) (1 - consumer risk = confidence)	Risks inversely proportional to sample size used.							

#### Notes:

- 1. Sample size dependent on total number of sample maintenance tasks selected as per paragraph A.10.4 of MIL-STD-471A.
- 2. Demonstration facility must have capability for insertion of simulated faults.

# Topic T8: FRACAS (Failure Reporting and Corrective Action System)

Early elimination of failure trends is a major contributor to reliability growth and attaining the needed operational reliability. To be effective, a closed loop coordinated process must be implemented by the system/equipment contractor. A description of the major events and the participant's actions is shown below.

Operators:	<ul> <li>Identify a problem, call for maintenance, annotate the incident.</li> </ul>
Maintenance:	• Corrects the problem, logs the failure.
Quality:	Inspects the correction.
Maintenance:	<ul> <li>Generates the failure report with supporting data (time, place, equipment, item, etc.)</li> </ul>
Quality:	<ul> <li>Insures completeness and assigns a travel tag for the failed item for audit control.</li> </ul>
R&M:	<ul> <li>Log all the failure reports, validate the failures and forms, classify the failures (inherent, induced, false alarm).</li> </ul>
R&M:	<ul> <li>Determine failure trends (i.e., several failures of the same or similar part).</li> </ul>
Design:	• Review operating procedures for error.
R&M:	Decide which parts will be destructively analyzed.
Physics of Failure:	Perform failure analysis to determine the cause of failure (i.e., part or
Quality:	external).
Design:	Inspect incoming test data for the part.
Vendor:	Redesign hardware, if necessary.
Quality:	New part or new test procedure.
R&M:	<ul> <li>Evaluate incoming test procedures, inspect redesigned hardware.</li> </ul>
	<ul> <li>Close the loop by collecting and evaluating post test data for reoccurrence of the failure.</li> </ul>
	Quality: Maintenance: Quality: R&M: R&M: Design: R&M: Physics of Failure: Quality: Design: Vendor: Quality:

	Design defects
	Manufacturing defects
	Physical or functional degradation below specification limits
	Intermittent or transient failures
	<ul> <li>Failures of limited life parts which occur before the specified life of the part</li> </ul>
	Failures which cannot be attributed to a specific cause
	Failure of built-in-test (BIT)
	The following types of failures should be defined as <i>nonrelevan</i> in the test plan:
	Failures resulting from improper installation or handling
	Failure of instrumentation or monitoring equipment which is external to equipment under test
	<ul> <li>Failures resulting from overstress beyond specification limits due to a test facility fault</li> </ul>
	Failures resulting from procedural error by technicians
	Failures induced by repair actions
	<ul> <li>A secondary failure which is the direct result of a failure of another part within the system.</li> </ul>

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-141

Торіс	Items to Be Addressed						
Test Ground Rules	<ul> <li>The following test ground rules should be stated in the test plan:</li> <li>Transient Failures - Each transient or intermittent failure is to be counted as relevant. If several intermittent or transien failures can be directly attributed to a single hardware or software malfunction which is corrected and verified during the test, then only a single failure will be counted as relevant.</li> </ul>						
	<ul> <li>Classification of Failures - All failures occurring during reliability testing, after contractor failure analysis, shall be classified as either relevant or nonrelevant. Based on the failure analysis, the contractor shall justify the failure a relevant or nonrelevant to the satisfaction of the procuring activity.</li> </ul>						
	<ul> <li>Pattern Failure - A pattern failure is defined as three or morrelevant failures of the same part in identical or equivaler applications whose 95th percentile lower confidence lim failure rate exceeds that predicted.</li> </ul>						
	<ul> <li>Malfunctions Observed During Test Set Up, Troubleshootin or Repair Verification - Malfunctions occurring during test set up, troubleshooting or repair verification tests shall not b considered as reliability test failures; however, suc malfunctions shall be recorded and analyzed by the contractor to determine the cause of malfunctions and to identify possibl design or part deficiencies.</li> </ul>						
	• Test Time Accumulation - Only the time accumulated durin the equipment power "on" portion of the test cycle shall b considered as test time, provided that all functions ar operating as required. Operating time accumulated outsid the operational cycles such as during tests performed t check out the setup or to verify repairs shall not be counted Also, time accumulated during degraded modes of operation shall not be counted.						
	<ul> <li>Design Changes to the Equipment:</li> <li>After test reject decision—With procuring activity approva the equipment may be redesigned and retested from tim zero.</li> </ul>						
	<ul> <li>Major design change prior to test reject—The contractor may stop the test for purposes of correcting a major problem. The test will restart from time zero after the design change has been made.</li> </ul>						
	<ul> <li>Minor design change prior to test reject—With procuring activity approval, the test may be halted for the purpose of making a minor design change. Test time will resume from the point at which it was stopped and the design change shall have no effect on the classification of previous failures. Minor changes made as a result of other testing may be incorporated, with procuring activity approva without declaring a failure of the equipment under test.</li> </ul>						

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-142

Торіс	Items to Be Addressed				
Test Ground Rules (cont'd)	• <i>Failure Categorization</i> - In order to clearly evaluate test results and identify problem areas, failure causes will be categorized as: (1) deficient system design, (2) deficient system quality control, and (3) deficient part design or quality.				
Test Logs	The following types of test logs should be described in the test plan:				
	• Equipment Data Sheets - used to record the exact values of all parameters measured during functional testing of the equipment.				
	• <i>Test Log</i> - a comprehensive narrative record of the required test events. All names and serial numbers of the equipments to be tested shall be listed before start of the test. An entry shall be made in the test log each time a check is made on the equipment under test, including data, time, elapsed time, and result (e.g., pass/malfunction indication/failure or etc.). An entry shall be made in the log whenever a check is made of the test facilities or equipments (such as accelerometers, thermocouples, input power, self-test, etc.). In the event of a failure or malfunction indication, all pertinent data, such as test conditions, facility conditions, test parameters and failure indicators, will be recorded. The actions taken to isolate and correct the failure shall also be recorded. Whenever engineering changes, or equipment changes are implemented, an entry shall be made in the log.				
	• Failure Summary Record - the failure summary record must chronologically list all failures that occur during the test. This record must contain all the information needed to reach an accept or reject decision for the test. Each failure must be described and all failure analysis data must be provided.				
	• Failure Report - for each failure that occurs, a failure report must be initiated. The report should contain the unit that failed, serial number, time, data, symptoms of failure and part or parts that failed.				

\*Most of these contents also apply to reliability growth testing.

# Topic T10: Reliability Test Procedure Checklist

Торіс	Items to Be Addressed
Equipment Operation	A general description of the equipment under test and its operation must be provided.
On/Off Cycle	Specific on/off times for each subsystem must be described.
Operation Modes	Specific times of operation for each system/subsystem mode must be described.
Exercising Methods	Methods of exercising all system/subsystem operation modes must be described. (Note: The system should be exercised continuously, not just power on).
Performance Verification Procedure	Step by step test procedures must be provided which fully describe how and when each performance parameter will be measured. Acceptable and unacceptable limits of each measured parameter should also be specified. All failure and out-of-tolerance indicators must be described and their location defined. Programmable alarm thresholds must be specified.
Failure Event Procedure	Step by step procedures must describe specific actions to be taken in the event of a trouble indication.
Adjustments and Preventive Maintenance	Step by step procedures must be provided which fully describe how and when all adjustments and preventive maintenance actions will be performed.

# Topic T12: Reliability and Maintainability Test Participation Criteria

# **Degree of Participation Depends On:**

- Availability of program resources to support on-site personnel
- How important R&M are to program success
- Availability and capability of other government on-site personnel

#### **Test Preliminaries**

- All test plans and procedures must be approved
- Agreements must be made among government personnel with respect to covering the test and incident reporting procedures
- Units under test and test equipment including serial numbers should be documented
- Working fire alarms, heat sensors and overvoltage alarms should be used
- Trial survey runs should be made per the approved test plan

#### **Test Conduct**

- Approved test plans and procedures must be available and strictly adhered to
- Equipment must not be tampered with
- Test logs must be accurately and comprehensively maintained
- Appropriate government personnel must be kept informed
- Only authorized personnel should be allowed in area (a list should be posted)
- Test logs, data sheets, and failure reports should be readily available for government review
- Units under test should be sealed to prevent tampering or unauthorized repair
- A schedule of inspections and visits should be maintained
- No repairs or replacements should be made without a government witness
- Government representatives must take part in failure review process
- Failed items should have "travel tags" on them
- Technical orders should be used for repair if available

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

# Topic T14: Design of Experiments

Design of Experiments is a very efficient, statistically based method of systematically studying the effects of experimental factors on response variables of interest. The efficiency is achieved through greatly reduced test time because the effects of varying multiple input factors at once can be systematically studied. The technique can be applied to a wide variety of product design, process design, and test and evaluation situations. Many books have been written on various experimental design strategies which cannot possibly be addressed in these few pages. It is the intent of this section only to give the reader a brief introduction to Design of Experiments by providing a single numerical example of what is called a fractional factorial design. Some other competing design strategies, each with their own strengths or weaknesses, include Full Factorial, Plackett-Burman, Box-Burman, and Taguchi.

Improved levels of reliability can be achieved through the use of Design of Experiments. Design of Experiments allows the experimenter to examine and quantify the main effects and interactions of factors acting on reliability. Once identified, the main factors affecting reliability (some of which may be uncontrollable, such as weather) can be dealt with systematically and scientifically. Their adverse effects on the system design can be minimized, thereby meeting performance specifications while remaining insensitive to uncontrollable factors. The following example illustrates the general procedure and usefulness of Design of Experiments. The example is broken down into a series of steps which illustrate the general procedure of designing experiments.

# Example: Fractional Factorial Design

An integrated circuit manufacturer desired to maximize the bond strength of a die mounted on an insulated substrate since it was determined that bonding strength problems were resulting in many field failures. A designed experiment was conducted to maximize bonding strength.

**Step 1 - Determine Factors:** It isn't always obvious which factors are important. A good way to select factors is through organized "brainstorming". Ishikawa charts (see Introduction) are helpful in organizing cause and effect related data. For our example, a brainstorming session was conducted and four factors were identified as affecting bonding strength: (1) epoxy type, (2) substrate material, (3) bake time, and (4) substrate thickness.

**Step 2 - Select Test Settings:** Often, as with this example, high and low settings are selected. This is referred to as a two-level experiment. (Design of Experiments techniques are often used for more than two-level experiments.) The four factors and their associated high and low settings for the example are shown in Table T14-1. The selection of high and low settings is arbitrary (e.g. Au Eutectic could be "+" and Silver could be "-").

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-148

Factor	Levels					
	Low (-)	High (+)				
А. Ероху Туре	Au Eutectic	Silver				
B. Substrate Material	Alumina	Beryllium Oxide				
C. Bake Time (at 90 <sup>°</sup> C)	90 Min	120 Min				
D. Substrate Thickness	.025 in	.05 in				

#### Table T14-1: Factors and Settings

**Step 3 - Set Up An Appropriate Design Matrix:** For our example, to investigate all possible combinations of four factors at two levels (high and low) each would require 16 (i.e., 2<sup>4</sup>) experimental runs. This type of experiment is referred to as a full factorial. The integrated circuit manufacturer decided to use a one half replicate fractional factorial with eight runs. This decision was made in order to conserve time and resources. The resulting design matrix is shown in Table T14-2. The Table T14-2 "+, -" matrix pattern is developed utilizing a commonly known Design of Experiments method called Yates algorithm. The test runs are randomized to minimize the possibility of outside effects contaminating the data. For example, if the tests were conducted over several days in a room where the temperature changed slightly, randomizing the various test trials would tend to minimize the effects of room temperature on the experimental results. The matrix is orthogonal which means that it has the correct balancing properties necessary for each factor's effect to be studied statistically independent from the rest. Procedures for setting up orthogonal matrices can be found in any of the references cited.

**Step 4 - Run The Tests:** The tests are run randomly at each setting shown in the rows of the array. The trial run order is determined by a random number table or any other type of random number generator. Resultant bonding strengths from testing are shown in Table T14-2.

Treatment <u>Combination</u>	Random Trial Run Order A		Fac B	tors C	D	Bonding Strength (psi) Y		
1	6	-	-	-	-	73		
2	5	-	-	+	+	88		
3	3	-	+	-	+	81		
4	8	-	+	+	-	77		
5	4	+	-	-	+	83		
6	2	+	-	+	-	81		
7	7	+	+	-	-	74		
8	1	+	+	+	+	90		
Mean $\overline{y} = \frac{yi}{8} = \frac{647}{8} = 80.875$								

#### Table T14-2: Orthogonal Design Matrix With Test Results

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-149

**Step 5 - Analyze The Results:** This step involves performing statistical analysis to determine which factors and/or interactions have a significant effect on the response variable of interest. As was done in Table T14-3, interactions and aliasing (aliasing is defined as two or more effects that have the same numerical value) patterns must be identified. The impact on the response variable caused by "A or BCD" cannot be differentiated between factor A or the interaction of BCD. This is the penalty which is paid for not performing a full factorial experiment (i.e., checking every possible combination). The determination of aliasing patterns are unique to each experiment and are described in many Design of Experiments textbooks. The assumption is usually made that 3-way interactions such as BCD are negligible. An Analysis of Variance is then performed as shown in Table T14-4 to determine which factors have a significant effect on bonding strength. The steps involved in performing an Analysis of Variance for this example are:

**5A. Calculate Sum of Squares:** From Table T14-3 the Sum-of-Squares for a two level, single replicate experiment is computed for all factors and interactions as illustrated below for the A factor (Epoxy Type).

Sum of Sq. (Factor A) =  $\frac{\# \text{ of treatment combinations}}{4} (Avg(+)-Avg(-))^2$ Sum of Sq. (Factor A) =  $\frac{8}{4}(2.25)^2 = 10.125$ 

**5B.** Calculate Error: The Sum of Squares for the error in this case is set equal to the sum of the Sum of Squares values for the three two-way interactions (i.e., AB or CD, AC or BD, BC or AD). This is known as pooling the error. This error is calculated as follows: Error = 1.125 + 1.125 + .125 = 2.375.

**5C. Determine Degrees of Freedom**. Degrees of Freedom is the number of levels of each factor minus one. Degrees of Freedom (df) is always 1 for factors and interactions for a two level experiment as shown in this simplified example. Degrees of Freedom for the error (df<sub>err</sub>) in this case is equal to 3 since there are 3 interaction Degrees of Freedom. df<sub>F</sub> denotes degrees of freedom for a factor.

**5D. Calculate Mean Square**. Mean Square equals the sum of squares divided by the associated degrees of freedom. Mean Square for a two level, single replicate experiment is always equal to the sum of squares for all factors. Mean Square for the error in this case is equal to the Sum of Squares error term divided by 3 (3 is the df of the error).

**5E.** Perform F Ratio Test for Significance. To determine the F ratio the mean square of the factor is divided by the mean square error (.792) from Table T14-4. F ( $\alpha$ , df<sub>F</sub>, df<sub>err</sub>) represents the critical value of the statistical F-distribution and is found in look-up tables in most any statistics book. Alpha ( $\alpha$ ) represents the level at which you are willing to risk in concluding that a significant effect is not present when in actuality it is. If the F ratio is greater than the looked up value of F ( $\alpha$ , df<sub>F</sub>, df<sub>err</sub>) then the factor

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-150

does have a significant effect on the response variable. (F (.1,1,3) = 5.54 in this case).

As a word of caution, the above formulations are not intended for use in a cookbook fashion. Proper methods for computing Sum of Squares, Mean Square, Degrees of Freedom, etc. depend on the experiment type being run and can be found in appropriate Design of Experiments reference books.

-								
Treatment Combination	A or BCD	B or ACD	AB or CD	C or ABD	AC or BD	BC or AD	D or ABC	Bonding Strength* y
1	-	-	+	-	+	+	-	73

# Table T14-3:Interactions, Aliasing Patterns andAverage "+" and "-" Values

\*The mean bonding strength calculated from this column is 80.875.

#### Table T14-4: Results of Analysis of Variance

Source	Sum of Squares	Degrees of Freedom	Mean Square	F ratio*	Significant Effect
Epoxy Type (A)	10.125	1	10.125	12.789	Yes
Substrate Material (B)	1.125	1	1.125	1.421	No
Bake Time (C)	78.125	1	78.125	98.684	Yes
Substrate Thickness (D)	171.125	1	171.125	216.158	Yes
A x B or C x D	1.125	1			
A x C or B x D	1.125	1			
B x C or A x D	0.125	1			
Error	2.375	3	.792		

\*Example Calculation: F = Mean Square/Error = 10.125/.792 = 12.789

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-151

**Step 6 - Calculate Optimum Settings:** From the Analysis of Variance, the factors A, C, and D were found to be significant at the 10% level. In order to maximize the response, i.e. bonding strength, we can determine optimum settings by inspecting the following prediction equation:

y = (mean bonding strength) + 2.25A + 6.25C + 9.25D

Since A, C, and D are the only significant terms they are then the only ones found in the prediction equation. Since A, C, and D all have positive coefficients they must be set at high to maximize bonding strength. Factor B, substrate material, which was found to be nonsignificant should be chosen based on its cost since it does not affect bonding strength. A cost analysis should always be accomplished to assure that all decisions resulting from designed experiments are cost-effective.

**Step 7 - Do Confirmation Run Test:** Since there may be important factors not considered or nonlinear effects, the optimum settings must be verified by test. If they check out, the job is done. If not, some new tests must be planned.

# Topic T15: Accelerated Life Testing

Accelerated life testing employs a variety of high stress test methods that shorten the life of a product or quicken the degradation of the product's performance. The goal of such testing is to efficiently obtain performance data that, when properly analyzed, yields reasonable estimates of the product's life or performance under normal conditions.

# Why Use It?

- Considerable savings of time and money
- Quantify the relationship between stress and performance
- Identify design and manufacturing deficiencies

## Why Not?

- Difficulty in translating the stress data to normal use levels
- High stress testing may damage systems
- Precipitated failures may not represent use level failures

#### **Test Methods**

Most accelerated test methods involving electronics are limited to temperature or voltage. However, other methods have included: acceleration, shock, humidity, fungus, corrosion, and vibration.

#### **Graphical Analysis**

The advantages are:

- Requires no statistics
- Easily translates the high stress data to normal levels
- Very convincing and easy to interpret
- Provides visual estimates over any range of stress
- Verifies stress/performance relations

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-153

The disadvantages are:

- Does not provide objectiveness
- Has statistical uncertainty
- Relies on an assumed relationship which may not fit the data

#### Test Design

All test conditions should be limited to three elevated stress levels (considering budget, schedule, and chamber capabilities) with the following conditions:

- Test stress should exceed maximum operating limits
- Test stress should not exceed maximum **design** limits
- Stress levels only for normal use failure modes

#### **Test Units**

The units shall be allocated to the particular stress levels so that most of the units are at the lower stress levels and fewer units at the higher. If 20 test units are available, a reasonable allocation would be 9 units at the lowest level and 7 and 4 at the higher levels. This allocation scheme is employed so that the majority of the test data is collected nearest to the operating levels of stress. Three units should be considered a minimum for the higher levels of stress; if fewer than 10 units are available for test, design for only two levels.

#### Data Analysis: Probability Plot

The operational performance (time before failure in most cases) of nearly all electronic and electromechanical systems can be described by either the Lognormal or Weibull probability density functions (pdf). The pdf describes how the percentage of failures is distributed as a function of operating time. The probability plot of test data is generated as follows:

- Rank the failure times from first to last for each level of test stress (nonfailed units close out the list).
- For each failure time, rank i, calculate its plotting position as:

$$P = 100 \left(\frac{i - .5}{n}\right)$$

Where n is the total number of units on test at that level.

• Plot P versus the failure time for each failure at each stress level on appropriately scaled graph paper (either Logarithmic or Weibull).

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-154

• Visually plot lines through each set (level of stress) of points. The lines should plot parallel, weighting the tendency of the set with the most data heaviest. If the lines do not plot reasonably parallel, investigate failure modes.

# Data Analysis: Relationship Plot

The relationship plot is constructed on an axis that describes unit performance as a function of stress. Two of the most commonly assumed relations are the Inverse Power and the Arrhenius Relationship. The relationship plot is done as follows:

- On a scaled graph, plot the 50% points determined from the probability plot for each test stress.
- Through these 50% points, plot a single line, projecting beyond the upper and lower points.
- From this plot locate the intersection of the plotted line and the normal stress value. This point, read from the time axis, represents the time at which 50% of the units will fail while operating under normal conditions.
- Plot the time determined in step three on the probability plot. Draw a line through this point parallel to those previously drawn. This resulting line represents the distribution of failures as they occur at normal levels of stress.

## **Example: Probability and Relationship Plots**

Consider an electronic device life test that demonstrates an Arrhenius performance/stress relationship that fails lognormally at any given level of stress. Engineers wish to determine the unit's reliability (MTBF) at 90°C (maximum operating temperature). There are 20 units available for test.

After reviewing the design and considering the potential failure modes, the engineers concluded that the units could survive at temperatures in excess of 230 °C without damage. The engineers did, however, estimate that non-regular failure modes will be precipitated above this temperature, therefore, 230 °C was established as the maximum test level with 150 °C and 180 °C as interim stress levels. The test units were allocated to three test levels and run for 1000 hours. The resulting failure times are shown in Table T15-1.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-155

	8							
*	9							

Table T15-1:	Test Results
--------------	--------------

\* Unit still operating at 1000 hours

The probability and relationship plots are shown in Figures T15-1 & T15-2. From Figure T15-2 it is estimated that 50% of the units will fail by 3500 hours while operating at 90 $^{\circ}$ C. Further, from Figure T15-1, it can be estimated that at 90 $^{\circ}$ C, 10% of the units will fail by 2200 hours and 10% will remain (90% failed) at 5000 hours.

This type of testing is not limited to device or component levels of assembly. Circuit card and box level assemblies can be tested in a similar manner. Generally, for more complex test units, the probability plot will be developed on Weibull paper, while the relationship plot will likely require a trial and error development utilizing several inverse power plots to find an adequate fit.

# Topic T16: Time Stress Measurement

Environmental factors, such as temperature, humidity, vibration, shock, power quality, and corrosion impact the useful lifetime of electronic equipment. Knowing the environmental conditions under which the equipment is operated provides insight into equipment failure mechanisms. The capability to measure environmental parameters will help reduce and control the incidence of Retest OK (RTOK) and Cannot Duplicate (CND) maintenance events which account for 35% to 65% of the indicated faults in Air Force avionics systems. Many of these RTOK and CND events are environmentally related and a record of the environmental conditions at the time of occurrence should greatly aid in the resolution of these events.

## Active Time Stress Measurement Devices (TSMD)

- **Module TSMD:** The module developed by the Rome Laboratory is physically 6" x 4" x 1.25" and measures and records temperature, vibration, humidity, shock, corrosion and power transients. This module operates independently of the host equipment and records and stores data for later retrieval.
- **Micro TSMD:** The micro version of the TSMD is a small hybrid circuit that is suitable for mounting on a circuit card in a Line Replaceable Unit (LRU). All the parameters measured by the module TSMD are recorded in the micro version.
- Fault Logging TSMD: A new advanced device has been developed that is suitable for circuit board mounting and includes environmental parameters being measured prior to, during, and after a Built-In-Test (BIT) detected fault or event. The environment data will be used to correlate faults with environmental conditions such as temperature, vibration, shock, cooling air supply pressure, and power supply condition to better determine what impact environment has on system failure.
- Quick Reliability Assessment Tool (QRAT): The objective of the effort is to build a stand-alone, compact, portable, easily attachable system for quick reaction measurement and recording of environmental stresses. The parameters it measures include voltage, temperature, vibration and shock. The system which includes a debrief laptop computer, an electronics module with internal sensors, a battery pack, remote sensors, various attachment plates, and will fit in a ruggedized suitcase. The electronics module is be 3" x 2" x 0.5" and contains the sensors, digital signal processor, and 512K bytes of EEPROM for storage of data. Three axis continuous vibration data will be recorded and stored in a power spectral density format. The user could choose to use either the sensors internal to the electronics module or the remote sensors. The debrief computer is used to tailor the electronics module to the specific needs of the user and to graphically display the collected data. Some potential uses for the collected data are: identification of environmental design envelopes, determination of loads and boundary

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-159

conditions for input into simulation techniques, and characterization of failures in specific systems.

#### **Passive Environmental Recorders**

- **High and Low Temperature Strip Recorders:** Strip recorders offer a sequence of chemical mixtures deposited as small spots on a paper. Each spot changes color at a predetermined temperature showing that a given value has been exceeded.
- **Temperature Markers:** Markers are available to measure temperature extremes. The marking material either melts or changes color at predetermined temperatures.
- **Humidity Strip Recorders:** Using crystals that dissolve at different humidity levels, a strip recorder is available that indicates if a humidity level has been surpassed.
- **Shock Indicators:** Single value indicators that tell when an impact acceleration exceeds the set point along a single axis.

## **Application, Active Devices**

- Avionic Environmental Stress Recording
- Transportation Stress Recording
- Flight Development Testing
- Warranty Verification
- Aircraft: A-10, A-7, B-1, and EF-111

# Appendix 1 Operational Parameter Translation

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-1

Because field operation introduces factors which are uncontrollable by contractors (e.g. maintenance policy), "contract" reliability is not the same as "operational" reliability. For that reason, it is often necessary to convert, or translate, from "contract" to "operational" terms and vice versa. This appendix is based on RADC-TR-89-299 (Vol I & II), "Reliability and Maintainability Operational Parameter Translation II" which developed models for the two most common environments, ground and airborne. The translation models are summarized in Table 1-1.

## Definitions

• Mean-Time-Between-Failure-Field (MTBF<sub>F</sub>) includes inherent maintenance events which are caused by design or manufacturing defects.

MTBF<sub>F</sub> = Total Operating Hours or Flight Hours Inherent Maintenance Events

• Mean-Time-Between-Maintenance-Field (MTBM<sub>F</sub>) consists of inherent, induced and no defect found maintenance actions.

 $MTBM_{F} = \frac{Total Operating Hours or Flight Hours}{Total Maintenance Events}$ 

 Mean-Time-Between Removals-Field (MTBR<sub>F</sub>) includes all removals of the equipment from the system.

MTBR<sub>F</sub> = Total Operating Hours or Flight Hours Total Equipment Removals

- $\theta_{P}$  = is the predicted MTBF (i.e. MIL-HDBK-217).
- $\theta_{D}$  = is the demonstrated MTBF (i.e. MIL-HDBK-781).
- $R_F^{U}$  = is the equipment type or application constant.
- C' = is the power on-off cycles per mission.
- D = is the mission duration.

# **Equipment Operating Hour to Flight Hour Conversion**

For Airborne Categories - MTBF<sub>F</sub> represents the Mean-Time-Between-Failure in Equipment Operating Hours. To obtain MTBF<sub>F</sub> in terms of flight hours (for both fighter and transport models), divide MTBF<sub>F</sub> by 1.2 for all categories except counter measures. Divide by .8 for counter measure equipment.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-3

## Example

Estimate the MTBM of a fighter radar given a mission length of 1.5 hours, two radar shutdowns per mission and a predicted radar MTBF of 420 hours. Using Model 1B in Table 1-1,

MTBM<sub>F</sub> = 
$$\theta_{P}$$
.<sup>64</sup> R<sub>F</sub>  $(\frac{C}{D})^{-.57}$  = (420 hr.).<sup>64</sup> 1.7  $(\frac{2 \text{ cyc.}}{1.5 \text{ hr.}})^{-.57}$ 

 $MTBM_F = 69$  equipment operating hours between maintenance.

Since this is below the dependent variable lower bound of (.24)(420) = 101 hours, the calculated MTBM<sub>F</sub> is correct. Since this equipment is often turned on for pre and post flight checkout, the number of flight hours between maintenance is somewhat less than the actual equipment operating hours. The number of flight hours between maintenance is approximately 69/1.2 = 58 hours.

# Appendix 2 Example R&M Requirement Paragraphs

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-7

# Example Reliability Requirements for the System Specification

# **R.1 Reliability Requirements**

**Guidance:** The use of the latest versions and notices of all military specifications, standards and handbooks should be specified. See Toolkit Section R, "Requirements" for task tailoring guidance. When specifying an MTBF, it should be the "upper test MTBF ( $\theta_0$ )" as defined in MIL-STD-781. When specifying MTBCF, the maintenance concept needs to be clearly defined for purposes of calculating reliability of redundant configurations with periodic maintenance. If immediate maintenance will be performed upon failure of a redundant element then specifying the system MTTR is sufficient. If maintenance is deferred when a redundant element fails, then the length of this deferral period should be specified.

**R.1.1 Mission Reliability:** The (system name) shall achieve a mean-timebetween-critical-failure (MTBCF) of \_\_\_\_\_ hours under the worst case environmental conditions specified herein. MTBCF is defined as the total uptime divided by the number of critical failures that degrade full mission capability (FMC). FMC is that level of performance which allows the system to perform its primary mission without degradation below minimum levels stated herein. For purposes of analyzing redundant configurations, calculation of MTBCF shall reflect the expected field maintenance concept.

**R.1.2 Basic Reliability:** The (system name) shall achieve a series configuration mean-time-between-failure (MTBF) of \_\_\_\_\_ hours under the worst case environmental conditions specified herein. The series configuration MTBF is defined as the total system uptime divided by the total number of part failures.

**R.1.3 Reliability Configuration:** The reliability requirements apply for the delivered configuration of the system. Should differences exist between this configuration and a potential production configuration, all analyses shall address the reliability effects of the differences.

*Guidance:* If equipment or system performance criteria are not stated elsewhere in the statement of work or specification, the following paragraph must be included.

**R.1.4 Reliability Performance Criteria:** The minimum performance criteria that shall be met for full mission capability of the *(system name)* system is defined as (specify full mission capability).

**R.1.5 Reliability Design Requirements:** Design criteria and guidelines shall be developed by the contractor for use by system designers as a means of achieving the required levels of reliability.

*Guidance:* For more critical applications, Level II or I, derating should be specified. See Topic D1 for derating level determination. Baseline thermal requirements such as ambient and extreme temperatures, pressure extremes, mission profile and

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-9

duration, temperature/pressure rates of change and maximum allowable temperature rise should be specified.

**R.1.5.1 Thermal Management and Derating:** Thermal management (design, analysis and verification) shall be performed by the contractor such that the reliability quantitative requirements are assured. RADC-TR-82-172, "RADC Thermal Guide for Reliability Engineers," shall be used as a guide. Derating criteria shall be established for each design such that all parts used in the system are derated to achieve reliability requirements. As a minimum, Level 3 of AFSC Pamphlet 800-27 "Part Derating Guidelines" shall be used for this design.

*Guidance:* If the system is for airborne use, MIL-STD-5400 must be referenced in place of MIL-E-4158 (ground equipment).

**R.1.5.2 Parts Selection:** All parts employed in the manufacture of the system shall be selected from the government generated and maintained Program Parts Selection List (PPSL), Electrical/Electronic Parts and the PPSL for Mechanical Parts. Parts not covered by the above referenced PPSLs shall be selected in accordance with MIL-E-4158 and MIL-STD-454 and require approval by the procuring activity.

- a. **Microcircuits.** Military standard microcircuits must be selected in accordance with Requirement 64 of MIL-STD-454. All non-JAN devices shall be tested in accordance with the Class B screening requirements of MIL-STD-883, Method 5004 and 5008, as applicable. All device types shall be tested to the quality conformance requirements of MIL-STD-883, Method 5005 and 5008 Class B.
- b. Semiconductors. Military standard semiconductors must be selected in accordance with Requirement 30 of MIL-STD-454. All non-JANTX devices shall be screened in accordance with Table II of MIL-S-19500. All device types shall be tested to the Group A, Table III and Group B, Table IV quality conformance requirements of MIL-S-19500, as a minimum. The following device restrictions apply:
  - (1) Only solid glass metallurgically bonded axial lead diodes and rectifiers shall be used.
  - (2) TO-5 packages shall be limited to the solid metal header type.
  - (3) All semiconductor device junctions must be protected and no organic or desiccant materials shall be included in the package.
  - (4) Devices using aluminum wire shall not use thermocompression wedge bonding.
  - (5) Aluminum TO-3 packages shall not be used.
  - (6) Germanium devices shall not be used.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-10

c. **Electrostatic Sensitive Parts.** Certain types of integrated circuits are susceptible to electrostatic discharge damage. Appropriate discharge procedures are necessary when handling, storing or testing these parts and design selections of desired devices should include a consideration of the effectiveness of the input or other protective elements included in the device design.

**R.1.6 Reliability Test and Evaluation:** The quantitative reliability levels required by paragraph (R.1) shall be verified by the following:

**R.1.6.1** The final approved reliability analyses for the various configurations and worst case environments shall demonstrate compliance with the quantitative requirements cited in paragraph (R.1).

**R.1.6.2** The contractor shall demonstrate that the reliability (mission and/or basic) requirements have been achieved by conducting a controlled reliability test in accordance with MIL-HDBK-781 Test Plan (specify MIL-HDBK-781 Test Plan). (See Topic T5 and Appendix 5 for Plan Selection). The lower test (MTBCF and/or MTBF) to be demonstrated shall be \_\_\_\_\_ hours tested in a \_\_\_\_\_ environment. Relevant failures are defined as any malfunction which causes loss or degradation below the performance level specified for the (equipment/system) and can be attributed to design defect, manufacturing defect, workmanship defect, adjustment, deterioration or unknown causes. Nonrelevant failures are failures caused by installation damage, external test equipment failures, mishandling, procedural errors, dependent failures and external prime power failures.

**Guidance:** A growth test may apply if the next phase is production. If one is required, it's appropriate to require a higher risk (e.g., 30 percent) demonstration test. See RADC-TR-84-20 "Reliability Growth Testing Effectiveness," Topic T4 and Appendix 6 for further guidance.

**R.1.6.3** The contractor shall conduct a controlled fixed length dedicated reliability growth test of \_\_\_\_\_ hours using MIL-HDBK-189 as a guide. The test shall be at the same environmental conditions as the RQT. Although there is no pass/fail criteria, the contractor shall track the reliability growth process to ensure improvement is taking place by effective implementation of corrective action.

**Guidance:** See Electronic Systems Center Report TR-85-148, "Derated Application of Parts for ESC Systems Development" (Attachment 2) for a recommended derating verification procedure.

**R.1.6.4** The contractor shall verify the thermal and electrical stresses on \_\_\_\_\_\_ percent (3 to 5 percent sample is typical) of the semiconductor and microcircuit parts by measurement while the equipment is operated at the worst case environment, duty cycle and load. The results of the measurements shall be compared to the derating requirements and the verification shall be considered successful if measured values are less than specified derated levels.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-11

## Example Reliability Requirements for the Statement of Work

## **R.2 Reliability Program Tasks**

**R.2.1 Reliability Program:** The contractor shall conduct a reliability program in accordance with MIL-STD-785 including the following tasks as a minimum to assure reliability consistent with state-of-the-art.

**R.2.2** Subcontractor Control: The contractor shall establish management procedures and design controls including allocation of requirements in accordance with Task 102 of MIL-STD-785 which will insure that products obtained from subcontractors will meet reliability requirements.

**R.2.3 Reliability Design Reviews:** The status of the reliability design shall be addressed at all internal and external design reviews. Task 103 of MIL-STD-785 shall be used as a guide.

**R.2.4 Failure Reporting, Analysis and Corrective Action System (FRACAS):** The contractor shall establish, conduct and document a closed loop failure reporting, analysis and corrective action system for all failures occurring during system debugging, checkout, engineering tests and contractor maintenance. Failure reports shall be retained by the contractor and failure summaries provided to the procuring activity thirty days after start of system engineering test and evaluation, and updated monthly thereafter. Failure reporting shall be to the piece part level.

**R.2.5 Reliability Modeling:** The contractor shall develop reliability models for all system configurations in accordance with Task 201 of MIL-STD-785 and Task 101 and 201 of MIL-STD-756. The specific mission parameters and operational constraints that must be considered are: \_\_\_\_\_ (or reference applicable SOW and specification paragraphs).

**R.2.6 Reliability Allocations:** Reliability requirements shall be allocated to the LRU level in accordance with Task 202 of MIL-STD-785.

**R.2.7 Reliability Prediction:** The contractor shall perform reliability predictions in accordance with (*Task 201 (basic reliability)*)) and/or (*Task 202 (mission reliability)*)) of MIL-STD-756. The specific technique to be used shall be method 2005 parts stress analysis of MIL-STD-756. Electronic part failure rates shall be used from MIL-HDBK-217 and nonelectronic part failure rates from RADC-TR-85-194. All other sources of part failure rate data shall require review and approval of the procuring activity prior to use. A \_\_\_\_\_\_ environmental factor, worst case operating conditions and duty cycles shall be used as a baseline for developing part failure rates. The results of the thermal analysis shall be included and shall provide the temperature basis for the predicted reliability. The part quality grade adjustment factor used shall be representative of the quality of the parts selected and applied for this system procurement.

**R.2.8 Parts Program:** The contractor shall establish and maintain a parts control program in accordance with Task 207 of MIL-STD-785 and Procedure 1 of MIL-STD-965. Requests for use of parts not on the government generated and

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-12

maintained PPSL shall be submitted in accordance with the CDRL. Amendments to the PPSL as a result of such requests, after procuring activity approval, shall be supplied to the contractor by the Program Contracting Officer not more often than once every 30 days.

**Guidance:** The level of detail of the FMECA must be specified (e.g., part, circuit card, etc.). The closer the program is to full scale engineering development, the greater the level of detail needed.

**R.2.9 Failure Modes, Effects and Criticality Analysis (FMECA):** The contractor shall perform a limited FMECA to the \_\_\_\_\_ level to identify design weaknesses and deficiencies. Potential failure modes shall be identified and evaluated to determine their effects on mission success. Critical failures shall be investigated to determine possible design improvements and elimination means. MIL-STD-785, Task 204 shall be used as a guide.

**Guidance:** Reliability critical items should be required where it's anticipated that the design will make use of custom VLSI, hybrids, microwave hybrids and other high technology nonstandard devices. See Topic D5 for a critical item checklist.

**R.2.10 Reliability Critical Items:** Task number 208 of MIL-STD-785 applies. The contractor shall prepare a list of critical items and present this list at all formal reviews. Critical items shall include: items having limited operating life or shelf life, items difficult to procure or manufacture, items with unsatisfactory operating history, items of new technology with little reliability data, single source items, parts exceeding derating limits, and items causing single points of failure.

**R.2.11 Effects of Storage, Handling, Transportation:** The contractor shall analyze the effects of storage, handling and transportation on the system reliability.

**R.2.12 Reliability Qualification Test:** The contractor shall demonstrate compliance with the quantitative reliability requirements in accordance with MIL-STD-785 Task 302. Test plans and reports shall be developed and submitted.

**R.2.13 Reliability Development/Growth Test:** Test plans that show data tracking growth, testing methods and data collection procedures shall be developed and submitted for the Growth Test Program.

**Guidance:** When specifying ESS, the level (circuit card, module, assembly, etc.) at which the screening is to be performed must be specified. Different levels of screening should be performed at different hardware assembly levels. See R&M 2000 guidelines in Section T for recommended screening as a function of hardware assembly level.

**R.2.14 Environmental Stress Screening:** Task number 301 of MIL-STD-785 applies. A burn-in test of \_\_\_\_\_\_ (specify the number of hours or temperature cycles) at \_\_\_\_\_\_ temperature and \_\_\_\_\_\_ vibration level extremes shall be performed at the \_\_\_\_\_\_ level. At least \_\_\_\_\_\_ (hours/cycles) of failure free operation shall be experienced before termination of the burn-in test for each unit. DOD-HDBK-344, ESS of Electronic Equipment, shall be used as a guide.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-13

### Example Maintainability Requirements for the System Specification

#### M.1 Maintainability Requirements

**M.1.1 Maintainability Quantitative Requirements:** The (*system name*) shall be designed to achieve a mean-corrective-maintenance-time ( $M_{CT}$ ) of no greater than \_\_\_\_\_ minutes and a maximum-corrective maintenance-time ( $M_{MAXCT}$ ) of no greater than \_\_\_\_\_ minutes (95th percentile) at the (*specify organization, intermediate or depot level*), when repaired by an Air Force maintenance technician of skill level \_\_\_\_\_ or equivalent.

**Guidance:** Preventive maintenance requirements are considered an option to be implemented when items are used in the design that are subject to wearout, alignment, adjustment or have fault tolerance that must be renewed. If the option is exercised, then attach the paragraph below to *M*.1.1.

**M.1.2** Preventive maintenance shall not exceed \_\_\_\_\_ minutes for each period and the period shall not be more frequent than every \_\_\_\_\_.

**M.1.3** The mean time to restore system (MTTRS) following a system failure shall not be greater than \_\_\_\_\_. MTTRS includes all corrective maintenance time and logistics delay time.

**M.1.4** The mean maintenance manhours (M-MMH) shall not be greater than \_\_\_\_\_\_ hours per year. M-MMH is defined as follows: (operating hours per year) \_ (system MTBF) (system MTTR) (number of maintenance personnel required for corrective action).

**Guidance:** Above definition of M-MMH assumes that a repair is made when each failure occurs. If a delayed maintenance concept is anticipated through the use of fault tolerance, then MTBCF should be used (instead of MTBF) in the above definition. If only a limited number of site visits are allowed, then this value should be used in the above definition in place of "operating hours per year \_ system MTBF."

**M.1.5 Maintainability Design:** The system design shall provide modularity, accessibility, built-in-test (BIT) and other maintainability features to provide installation simplicity, ease of maintenance and the attainment of the maintainability requirements (both corrective and preventive). Line Replaceable Units (LRUs) such as printed circuit boards or assemblies shall be replaceable without cutting or unsoldering connections. All plug-in modules shall be mechanically keyed/coded to prevent insertion of a wrong module.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-14

**M.1.5.1 Testability:** The system design shall be partitioned based upon the ability to isolate faults. Each item shall have sufficient test points for the measurement or stimulus of internal circuit nodes to achieve the capability of detecting 100 percent of all permanent failures using full resources. Automatic monitoring and diagnostic capabilities shall be provided to show the system status (operable, inoperable, degraded) and to detect 90 percent of all permanent failures. The false alarm rate due to self-test circuitry shall be less than 1 percent of the series failure rate. Self-test circuitry shall be designed to correctly isolate the fault to a group of four (4) LRUs, or less, 95 percent of the time.

**M.1.6 Maintainability Test and Evaluation:** Maintainability requirements for the *(system name)* shall be verified by the following:

**M.1.6.1 Maintainability Analysis.** The results of the final maintainability prediction shall be compared to the quantitative requirements and achievement determined if the predicted parameters are less than or equal to the required parameters.

**M.1.6.2 Maintainability Demonstration**. A maintainability demonstration shall be performed in accordance with Test Method \_\_\_\_\_ (Test Method 9 is commonly specified, see Appendix 7 for further guidance) of MIL-STD-471. A minimum sample size of 50 tasks shall be demonstrated. The consumer's risk for the maintainability demonstration shall be equal to 10 percent. Fault detection and isolation requirements shall be demonstrated as part of the maintainability test.

**M.1.6.3 Testability Demonstration.** A testability demonstration shall be performed on the *(system name)* in accordance with Notice 2 of MIL-STD-471A.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-15

### Example Maintainability Requirements for the Statement of Work

#### M.2 Maintainability Program Tasks

**M.2.1 Maintainability Program:** The contractor shall conduct a maintainability program in accordance with MIL-STD-470 appropriately tailored for full scale development including the following tasks as a minimum to assure maintainability consistent with the requirements.

**M.2.2 Testability Program:** Testability characteristics and parameters are related to, and shall be treated as part of the maintainability program. The contractor shall conduct a testability program in accordance with MIL-STD-2165 appropriately tailored for FSD including the following tasks as a minimum to assure testability consistent with the requirements.

**M.2.3 Maintainability Design Review:** The status of the maintainability/ testability design shall be addressed at all internal and external design reviews.

**M.2.4 Subcontractor Control:** The contractor shall specify maintainability requirements to all subcontractors to insure that *(equipment/system name)* requirements of this program are attained. Task 102 of MIL-STD-470 shall be used as a guide.

**M.2.5 Maintainability/Testability Modeling:** The contractor shall establish a maintainability model using MIL-STD-470, Task 201 which reflects the construction and configuration of the FSD design. Linkages with MIL-STD-2165, Task 201 to relate testability/diagnostic design characteristics to maintainability parameters shall be provided.

**M.2.6 Maintainability Prediction:** The contractor shall predict maintainability figures of merit using Procedure V of MIL-HDBK-472 (Notice 1) at the on equipment level. MIL-STD-470, Task 203 shall be used as a guide.

**M.2.7 Maintainability/Testability Design Criteria:** The contractor shall develop design criteria to be used in the design process to achieve the specified maintainability and testability requirements. In addition, a design analysis showing failure modes, failure rates, ease of access, modularity and the capability to achieve the fault detection/isolation requirement shall be provided. RADC-TR-74-308 "Maintainability Engineering Design Handbook," RADC-TR-82-189 "RADC Testability Notebook," Task 202 of MIL-STD-2165 and Task 206 of MIL-STD-470A shall be used as a guide.

**Guidance:** Maintainability demonstration reports are only necessary if a maintainability test is specified in the maintainability specification requirements.

**M.2.8 Maintainability/Testability Demonstration:** A test plan and test report shall be submitted by the contractor. Task 301 of MIL-STD-470 and Task 301 of MIL-STD-2165 shall be used as guides.

Appendix 3 R&M Software Tools

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-17

Several hundred R&M software tools exist throughout Government, industry and academia. Table 3-1 lists software tool types with associated supplier reference numbers. The numbered list of suppliers follows. The list includes addresses and telephone numbers confirmed to be accurate as of Aug 92. The Rome Laboratory doesn't in any way endorse or encourage use of any specific supplier's tools listed. Potential software tool users should thoroughly research any claims made by software suppliers and carefully study their own needs before obtaining any software. Further information on R&M software tools can be obtained in the reports referenced below. The reports contain data relative to software tool's hardware requirements, claimed capabilities, interface capabilities, demonstration package availability and price.

#### **R&M Software Tool References**

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-21

### Appendix 4 Example Design Guidelines

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-23

This Appendix contains an example set of design guidelines structured to include verification methods. These guidelines are an example only and don't apply to all situations.

#### a. Thermal Design

#### (1) Integrated Circuit Junction Temperatures

**Design Guidelines**: The design of the environmental cooling system (ECS) should be capable of maintaining an average integrated circuit junction temperature of 55°C or less under typical operating conditions. Under worst case steady state conditions, components should operate at least 50°C below their rated maximum junction temperature.

**Analysis Recommendation:** Thermal finite element analysis should be performed to project operating temperatures under specified environmental conditions. The analysis should consider ECS performance, environmental impacts, and system thermal design. Average junction temperatures should include all integrated circuits within the system. Average temperature rise should include all components on an individual module.

**Test Recommendations:** Thermally instrumented observations should be made of components under specified environmental conditions. Instrumentation can be by direct contact measurement or by infrared photography.

#### (2) Thermal Gradients

**Design Guideline:** The maximum allowable temperature rise from any junction to the nearest heat sink should be 25°C. The average temperature rise from integrated circuit junctions to the heat sink should be no greater than 15°C. To minimize gradients, more complex and power-intensive devices should be placed to minimize their operating temperature.

**Analysis Recommendation:** Automated design tools that perform component placement should be programmed to produce this result. A thermal finite element analysis should be used to evaluate the projected thermal gradient under the specified environmental conditions.

**Test Recommendation:** Thermally instrumented observation of components under specified environmental conditions. Instrumentation can be by direct contact measurement or by infrared photography.

#### (3) Thermal Expansion Characteristics

**Design Guideline:** Component and board materials should be selected with compatible thermal coefficients of expansion (TCE). Additionally, coldplate materials should be selected for TCE compatibility with the attached printed wiring board. TCE mismatch results in warpage of the laminated assembly, which can reduce module clearances and stress circuit board component leads and solder joints.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-25

**Analysis Recommendation:** A finite element analysis should be performed to identify the stress patterns in the solder joints attaching the components to the board. TCE compatibility should be evaluated for the components, circuit board, and coldplate.

**Test Recommendation:** Environmental stress tests should be utilized in the development phase to verify the design analysis and environmental stress screening should be used in production to ensure consistency throughout the production cycle.

#### (4) Heat Transport Media

**Design Guideline:** The design should use a thermal conduction medium that is integral to the mechanical design of the board or module. Heat pipes, metal rails or internal planes are examples of thermally conductive media. The unit should meet temperature design requirements by cooling through the integral thermal conduction medium without depending on any other heat loss.

**Analysis Recommendation:** Thermal finite element analysis should be used to project heat flow under specified environmental conditions. Modules employing heat pipes for cooling should meet operating temperature requirements when the module heat sink is inclined at an angle of 90 degrees from the horizontal.

**Test Recommendation:** Thermally instrumented observation should be made of components under specified environmental conditions. Instrumentation can be by direct contact measurement or by infrared photography.

#### (5) Component Attachment

**Design Guideline:** Surface contact should be maximized between the component and the heat transport media. This can be achieved by direct pressure thermal compounds or solder. The technique used should be reversible for component removal during board repairs such that damage is not induced to nearby devices. If a thermal compound is used, it should not migrate or react with other components during testing or service use.

**Analysis Recommendation:** Specialized stress analyses should be performed to quantify thermal and mechanical stresses involved in removing the component from the board after production installation.

**Test Recommendation:** Demonstration of repair techniques should be performed early in the development phase.

#### (6) Thermal Cycling

**Design Guideline:** The unit should be designed to dampen its thermal response to the thermal excursions required by the specification. This can be achieved by using a large thermal mass or by using the cooling medium to insulate the unit from its environment to the maximum extent possible.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-26

**Analysis Recommendation:** Thermal finite element analysis to project heat flow and temperature excursions under specified environmental conditions.

**Test Recommendation:** Thermally instrumented observation of components under specified environmental excursions. Instrumentation can be by direct contact measurement or by infrared photography.

#### b. Testability Design

#### (1) Bottom-up Fault Reporting

**Design Guideline:** Incorporate autonomous self-testing at the lowest levels that are technically feasible. Utilize positive indication to report chip, module and subsystem status. The design should not depend upon external stimuli to perform fault detection or isolation to a replaceable element.

**Analysis Recommendation:** As soon as automated testability analysis tools become available, they should be used for the applicable engineering design workstations.

**Test Recommendation:** Hardware demonstration should be conducted early in the development phase to verify simulation results through the insertion of faults using the currently available version of the operational program, firmware and microcode.

#### (2) Fault Logging

**Design Guideline:** Modules should contain a non-volatile fault log that can be accessed by a system maintenance controller or by test equipment. The use of the fault log will improve reliability by reducing depot "Cannot Duplicates." Failure of the fault log should not cause a critical system failure, but should be observable to the maintenance controller.

**Analysis Recommendation:** Compliance should be verified by inspection. Operation should be verified by simulation.

Test Recommendation: Not applicable.

#### (3) Start-up Built-in-Test (BIT)

**Design Guideline:** The module should execute a BIT internal diagnostic routine immediately after power-up or receipt of an "Execute BIT" command. BIT should provide a complete functional test of the module to the maximum extent possible without transmitting any signals on external interface media. BIT should provide a complete functional test of the module and should include:

- (1) Verification of internal data paths
- (2) Verify station physical address

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-27

- (3) Verify message identification process from system
- (4) Verify proper functioning of all internal memory and other components

Any failure encountered during execution of BIT should be retried at lease once to confirm the response. Any confirmed failures should prevent the module from becoming enabled. A failed module should respond only to "RESET," "Execute BIT," and "Report Status" commands.

**Analysis Recommendation:** System design simulation tools should be used to verify operation of the BIT. These tools should include fault simulations as well as operational simulation.

**Test Recommendation:** Hardware demonstration should be conducted early in the development phase to verify simulation results through insertion of faults using currently available versions of the operational program, firmware and microcode.

#### (4) Background Diagnostics

**Design Guideline:** During normal operation, the module should continuously monitor itself through a background diagnostic test. The background diagnostic should provide coverage to the maximum extent possible without interfering with normal station operation. Failure of any test in the background diagnostic should cause the module to re-execute the failed test to screen out transient anomalous responses. If the failure is confirmed, the module should become immediately disabled.

**Analysis Recommendation:** System design simulation tools should be used to verify operation of the BIT. These tools should include fault simulations as well as operational simulation.

**Test Recommendation:** Hardware demonstration should be conducted early in the development phase to verify simulation results through insertion of faults using currently available versions of the operational program, firmware and microcode. Hardware demonstration may be performed by physically inserting faults in a module or by instrumenting a module to allow insertion of faults through external methods.

#### c. Mechanical Packaging Design

#### (1) Mechanical Insertion/Extraction-Induced Stresses

**Design Guideline:** Each module should withstand, without damage or separation, a minimum force equal to at least 100 pounds on insertion and four ounces per contact on extraction. Additionally, the backplane for the assembly should withstand the same forces at all module positions applied repeatedly in any sequence with any combination of modules present or missing.

**Analysis Recommendation:** A mechanical loads analysis should be performed to verify compliance with the mechanical requirements.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-28

**Test Recommendation:** The total computed force should be applied to simulate module insertion and extraction. The force should be applied in 2 seconds and maintained for 15 seconds.

#### (2) Insertion/Extraction Durability

**Design Guideline:** Modules should be capable of withstanding 500 cycles of mating and unmating with no degradation of module performance. The module should also be capable of withstanding 500 cycles of lateral displacement to simulate the use of thermal clamping devices. The backplane of the module's host assembly should be capable of withstanding 500 of the same cycles on each of its module positions.

**Analysis Recommendation:** A mechanical loads analysis should be performed to verify compliance with the mechanical requirements.

**Test Recommendation:** Each module/backplane position should be subjected to 500 cycles of insertion/extraction. The maximum specified insertion and extraction forces should be applied in 2 seconds and maintained for 15 seconds. Five hundred lateral displacement cycles should be applied to the module.

#### (3) Mechanical Vibration-Induced Stresses

**Design Guideline:** The larger components are more susceptible to mechanical stresses because they have a larger mass and because they are more constrained by the high number of pin-outs that act as attachment points. Module stiffness should be maximized to prevent board flexing resulting in stress fractures at the solder joints or component leadframe.

**Analysis Recommendation:** Mechanical finite element analysis should be performed to identify module characteristics throughout the specified vibrational environment.

**Test Recommendation:** Developmental units should be specially instrumented with accelerometers early in the development program. These units could use dummy masses attached using the intended production technique. Standard endurance and qualification tests should be performed in accordance with MIL-STD-810, "Environmental Test Methods and Engineering Guidelines."

#### (4) Module Torque Stresses

**Design Guidelines:** The module should be capable of withstanding a 6 inchpound torque applied in 2 seconds and maintained for 15 seconds in both directions along the header in a direction perpendicular to the plane of the header without detrimental effect to the mechanical or electrical properties of the module.

**Analysis Recommendation:** A mechanical loads analysis should be performed to verify compliance with the mechanical requirements.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-29

**Test Recommendation:** The required torque should be applied in 2 seconds and maintained for 15 seconds. During the time the torque is applied, the module should be rigidly supported with a zone between the interface plane and 0.5 inch above the interface panel.

#### (5) Module Cantilever Load

**Design Guideline:** The module should be capable of withstanding a force of 2 pounds applied perpendicular to the header height along the center line midway between the two extractor holes.

**Analysis Recommendation:** A mechanical loads analysis should be performed to verify compliance with the mechanical requirements.

**Test Recommendation:** The required force should be applied in two directions and should be applied in 2 to 10 seconds and maintained for 10 to 15 seconds without detrimental effect to the header structure.

#### (6) Module Retention

**Design Guideline:** Module retention techniques must be carefully designed to integrate the insertion mechanism, required connector insertion force, thermal contact area, and extraction mechanism. Conventional electronics have required the same considerations, but to a lesser degree because of their more conventional housings.

**Analysis Recommendation:** Specialized analyses should be used to quantify torque requirements and limitations of the wedge-clamping device, lever moments of insertion or extraction devices, tolerance buildups of the module slot and connector placement and mechanical deflections of the backplane.

**Test Recommendations:** Standard endurance and qualification tests in accordance with MIL-STD-810, "Environmental Test Methods and Engineering Guidelines."

#### (7) Connector Contact Integrity

**Design Guideline:** Each contact pin, as mounted in the connector, should withstand a minimum axial force of 20 ounces.

**Analysis Recommendation:** A mechanical loads analysis should be performed to verify compliance with the mechanical requirements.

**Test Recommendation:** The required force should be applied in 2 seconds along the length of the contact in either direction and maintained for 15 seconds.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-30

#### (8) Connector Float

**Design Guideline:** The connector-to-module interface should be sufficiently flexible to compensate for specified misalignments or tolerance buildup between the module and the backplane connector shells.

**Analysis Recommendation:** Tolerance review should be performed early in design process.

**Test Recommendation:** Demonstration testing can be performed easily during the initial mechanical design phase.

#### (9) Keying Pin Integrity

**Design Guideline:** When installed in the module, the keying pins should meet the following integrity requirements. Each keying pin should withstand a:

- Torque of 20 inch-ounces
- Pullout force of 9 pounds
- Pushout force of 40 pounds
- Cantilever load of 10 pounds

**Analysis Recommendation:** A mechanical loads analysis should be performed to verify compliance with the mechanical requirements.

**Test Recommendation:** The required forces should be applied to the keying pin in 2 seconds and maintained for 15 seconds.

#### d. Power Supply Design

#### (1) **Overcurrent Protection**

**Design Guideline:** The power supply should supply 125 percent of its rated output for  $2 \pm 0.25$  seconds, after which the power supply will shut down (shut down is defined as all outputs at less than 1 mv and 1 ma current, but all status and control lines still operating). Operation should not resume until the power supply is reset. In addition, the power supply outputs should be short circuit protected.

**Analysis Recommendation:** Compliance with the specified operation should be verified throughout the design process.

**Test Recommendation:** Specified operation of the protective device should be induced by application of the anomalous condition protected against. Correct operation of the protective device should be observed. Normal specified power supply operation should be verified after removal of the anomalous condition.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-31

#### (2) Overvoltage Protection

**Design Guideline:** The output should be sensed for overvoltage. An overvoltage on the output should immediately shut down the power supply. Operation should not resume until the power supply is reset. The overvoltage limits should be compatible with device logic absolute maximum limits. The overvoltage protection and sense circuits should be constructed such that an overvoltage on a failed power supply will not cause any other paralleled power supply to also shut down.

**Analysis Recommendation:** Compliance with the specified operation should be verified throughout the design process.

**Test Recommendation:** Specified operation of the protective device should be induced by application of the anomalous condition protected against. Correct operation of the protective device should be observed. Normal specified power supply operation should be verified after removal of the anomalous condition.

#### (3) Abnormal Thermal Operation

**Design Guideline:** In the event of an above-normal internal temperature, the power supply should be capable of continued operation at a reduced power output. Thermal sense circuits should regulate the output to the extent necessary to keep semiconductor junctions at or below specified levels. The power supply should resume operation at rated output if internal temperatures return to normal.

**Analysis Recommendation:** Compliance with the specified operation should be verified throughout the design process.

**Test Recommendation:** Specified operation of the protective device should be induced by application of the anomalous condition protected against. Correct operation of the protective device should be observed. Normal specified power supply operation should be verified after removal of the anomalous condition.

#### (4) Thermal Shutdown

**Design Guideline:** When thermal limiting is no longer capable of maintaining internal temperature at an acceptable level, the power supply should automatically shut down. Operation should not resume until the power supply is reset. Temperature sense circuits should remain active during shut down.

**Analysis Recommendation:** Compliance with the specified operation should be verified throughout the design process.

**Test Recommendation:** Specified operation of the protective device should be induced by application of the anomalous condition protected against. Correct operation of the protective device should be observed. Normal specified power supply operation should be verified after removal of the anomalous condition.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-32

#### (5) Power Supply Status Reporting

**Design Guideline:** There should be an interface on each power supply module that will allow data communication between the power supply and a CPU located on a separate module. Each power supply module will be addressed individually. The data and control lines should interface to the power supply module through the backplane connector. The following power supply parameters should be read by the CPU:

- Overcurrent status
- Overvoltage status
- Thermal limiting mode status
- Thermal shutdown status
- Percentage of full output power available

The following commands should be issued by the CPU to the power supply module:

- Reset
- Percentage of full output power required

**Analysis Recommendation:** Compliance with the specified operation should be verified throughout the design process.

**Test Recommendation:** Specified operation of the protective device (i.e., monitoring mechanism and control) should be induced by application of the anomalous condition protected against. Correct operation of the protective device should be observed. Normal specified power supply operation should be verified after removal of the anomalous condition.

#### (6) Power Supply Input Protection

**Design Guideline:** The power supply should automatically shut down if the input voltage is not within the specified allowable range, and at any time when the control circuits in the power supply do not have adequate voltage to regulate the outputs. This should include the time during normal start-up when generators are not producing their normal output voltage.

**Analysis Recommendation:** Compliance with the specified operation should be verified throughout the design process.

**Test Recommendation:** Specified operation of the protective device should be induced by application of the anomalous condition protected against. Correct operation of the protective device should be observed. Normal specified power supply operation should be verified after removal of the anomalous condition.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-33

#### (7) Backplane Conditions

**Design Guideline:** A sufficient number of connector pins should be paralleled so that no backplane connector pin carries more than 5 amps of current.

**Analysis Recommendation:** Compliance with the specified operation should be verified throughout the design process.

Test Recommendation: Not applicable.

#### (8) M-of-N Power Supply Redundancy

**Design Guideline:** The quantity of power supplies for a system of functional elements should be determined to allow uninterrupted operation if one of the power supplies fails. When all power supplies are functional, they should share the system load equally by operating at reduced output. If the system power requirement is less than that available from one power supply, redundancy should not be used unless a critical function is involved.

**Analysis Recommendation:** Compliance should be verified by electrical loads analysis.

Test Recommendation: Not applicable.

#### (9) Current Sharing

**Design Guideline:** The power supplies should be constructed so that units which have the same output voltage may operate in parallel. The design should be such that power supply failures will not cause degradation of parallel power supplies. Each power supply should provide its proportional share ( $\pm 10\%$ ) of the total electric load required at the configured output voltage.

**Analysis Recommendation:** Compliance with the specified operation should be verified as a part of the design process.

**Test Recommendation:** A demonstration should be conducted under load to verify that the parallel power supplies power up and power down in unison. Failure and reset of one of the power supplies should be simulated or induced to demonstrate proper operation of the remaining units through the transition.

#### (10) **Protective Device Operation**

**Design Guideline:** During parallel operation, each power supply protective device should be capable of sensing and operating independently of the other power supplies. Master-slave type operation should not be permitted under any circumstances.

**Analysis Recommendation:** Compliance with the specified operation should be verified as a part of the design process.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-34

**Test Recommendation:** A demonstration should be conducted under load to verify proper operation of each protective device during parallel operation.

#### e. Memory Fault Tolerance

#### (1) Block Masking

**Design Guideline:** Known locations of defective memory should be mapped out of the memory directories. In this manner, permanently failed cells can be prevented from contributing to double error occurrences in combination with soft errors. At power-up or reinitialization, BIT should perform a memory test routine and leave a memory map of all good blocks. At the conclusion of the memory test routine, all words contained in the memory blocks marked good should have been initialized in an error free data pattern. Program loader software should make use of the good memory block map, the process memory mapping registers, and information stored in program file headers to load distributed operating systems and application programs into the remaining good areas of main memory. Repair or replacement of the module should not be required until the number of remaining good blocks of memory are insufficient to meet operational requirements.

**Analysis Recommendation:** An analysis should be performed to identify the optimum combination of component/bit mapping, hardware control and software control.

Test Recommendation: Not applicable.

#### (2) Error Detection/Correction

**Design Guideline:** As a minimum, single error correct/double error detect code should be used in large bulk semiconductor memories. It should be considered in any application involving large amounts of semiconductor memory, but may impose unacceptable speed and complexity penalties in some applications (e.g., CPU).

**Analysis Recommendation:** A detailed timing analysis should be conducted to determine the impact of this technique on the specific application.

**Test Recommendation:** System bench testing should be used to insert faults and confirm expected system operation.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-35

### Appendix 5 Reliability Demonstration Testing

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-37

**1.0 Reliability Demonstration Testing:** This appendix presents tables and examples which summarize the following:

- MIL-HDBK-781 "Reliability Test Methods, Plans and Environments for Engineering Development, Qualification and Production"
- Confidence Interval Calculations
- Poisson's Exponential Binomial Limits

**2.0 MIL-HDBK-781 Test Plans:** Tables 5-1 and 5-2 summarize standard test plans as defined in MIL-HDBK-781. These plans assume an exponential failure distribution. For nonexponential situations the risks are different.

The fixed length test plans (Table 5-1) must be used when the exact length and cost of the test must be known beforehand and when it is necessary to demonstrate a specific MTBF to a predetermined confidence level by the test as well as reach an accept/reject decision.

The probability ratio sequential test (PRST) plans (Table 5-2) will accept material with a high MTBF or reject material with a very low MTBF more quickly than fixed length test plans having similar risks and discrimination ratios. However, different MTBF's may be demonstrated by different accept decision points for the same test plan and the total test time may vary significantly.

Additional guidance on test plan selection is provided in Section T, Topic T5.

**2.1** Fixed Length Test Plan Example: If the design goal MTBF ( $\theta_0$ ) for a system is specified as 750 hours and Test Plan XID is chosen, the following statements can be made:

- a. There is a 20 percent probability of rejecting a system whose true MTBF is 750 hours (producers risk).
- b. There is a 20 percent probability of accepting a system whose true MTBF is 500 hours (consumers risk).
- c. The lower test MTBF ( $\theta_1$ ) is 500 hours (750/1.5).
- d. The duration of the test is 10,750 hours (21.5 x 500).
- e. The test will reject any system which experiences 18 or more failures.
- f. The test will accept any system which experiences 17 or less failures.

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

# Table 5-2: MIL-HDBK-781 PRST Reliability Demonstration Test Plan Summary

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-41

**2.2 PRST Test Plan Example:** If the design goal MTBF ( $\theta_0$ ) for a system is specified as 750 hours and Test Plan IID is chosen, the following statements can be made:

- a. There is a 20 percent probability of rejecting a system whose true MTBF is 750 hours (producers risk).
- b. There is a 20 percent probability of accepting a system whose true MTBF is 500 hours (consumers risk).
- c. The lower test MTBF ( $\theta_1$ ) is 500 hours (750/1.5).
- d. The minimum time to an accept decision is 2095 hours (4.19 x 500).
- e. The expected time to an accept decision is 5700 hours (11.4 x 500). (Expected time to decision based on assumption of a true MTBF equal to  $\theta_0$ ).
- f. The maximum time to reach an accept decision is 10950 hours (21.9 x 500).

**3.0** Confidence Level Calculation (Exponential Distribution): There are two ways to end a reliability test, either on a specified number of failures occurring (failure truncated), or on a set period of time (time truncated). There are usually two types of confidence calculations of interest, either one sided (giving the confidence that an MTBF is above a certain value) or two sided (giving the confidence that an MTBF is between an upper and lower limit). Table 5-4 provides a simple means to estimate one or two sided confidence limits. Multiply the appropriate factor by the observed total life (T) to obtain the desired confidence interval.

**Example 1 - Failure Truncated Test with Replacement:** Twenty items are tested and replaced until 10 failures are observed. The tenth failure occurs at 80 hours. Determine the mean life of the items and the one-sided and two-sided 95% confidence intervals for the MTBF.

**Solution:** The mean life is (20 items) (80 hours/items) / 10 failures = 160 hours. From Table 5-4, Note 2 applies, d = (2)(10) = 20. The following factors are obtained from the table:

95% two-sided lower factor = .0585 95% two-sided upper factor = .208 95% one-sided lower factor = .0635

Multipling these factors by 1600 total part hours (i.e., (20 items) (80 hours/item)) results in a 95% confidence that the MTBF is between 94 hours and 333 hours, or a 95% confidence that the MTBF is at least 102 hours.

### Table 5-4: Factors for Calculation of Mean Life Confidence

Intervals from Test Data

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-43

**Example 2 - Time Terminated Test without Replacement:** Twenty items are placed on test for 100 hours with seven failures occuring at the 10, 16, 17, 25, 31, 46 and 65 hour points. Determine the one-sided lower 90% confidence interval.

Solution: The total number of part hours accumulated is:

10 + 16 + 17 + 25 + 31 + 46 + 65 + (13 non-failed items) (100 hours) = 1510 hrs.

The MTBF is 1510 hours/7 failures = 216 hrs.

From Table 5-4, Note 3 applies, d = 2(7+1) = 16.

The factor from the table is .0848 for the 90% one-sided lower limit. Therefore, we are 90% confident that the MTBF is greater than (.0848)(1510 hours) = 128 hours.

**4.0 Poisson Distribution:** The Poisson distribution is useful in calculating the probability that a certain number of failures will occur over a certain length of time for systems exhibiting exponential failure distributions (e.g., non-redundant electronic systems). The Poisson model can be stated as follows:

$$P(r) = \frac{e^{-\lambda t} (\lambda t)^{r}}{r!}$$

where

P(r) = probability of *exactly* r failures occurring

- $\lambda$  = the true failure rate per hour (i.e., the failure rate which would be exhibited over an infinite period)
- t = the test time
- r = the number of failure occurrences
- e = 2.71828...,
- ! = factorial symbol (e.g.,  $4! = 4 \times 3 \times 2 \times 1 = 24$ , 0! = 1, 1! = 1)

The probability of exactly 0 failures results in the exponential form of this distribution which is used to calculate the probability of success for a given period of time (i.e.,  $P(0) = e^{-\lambda t}$ ). The probability of more than one failure occurring is the sum of the probabilities of individual failures occurring. For example, the probability of two or less failures occurring is P(0) + P(1) + P(2). Table 5-5 is a tabulation of exact probabilities used to find the probability of an exact number of failures occurring. Table 5-6 is a tabulation of *cumulative* probabilities used to find the probability of a specific number of failures, or less, occurring.

**4.1 Poisson Example 1:** If the true MTBF of a system is 200 hours and a reliability demonstration test is conducted for 1000 hours, what is the probability of accepting the system if three or less failures are allowed?

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-44

**Solution:** Expected number of failures =  $\lambda t = \frac{t}{MTBF} = \frac{1000}{200} = 5$ 

From Table 5-6, the probability of three or less failures (probability of acceptance) given that five are expected is .265. Therefore, there is only a 26.5 percent chance that this system will be accepted if subjected to this test.

**4.2 Poisson Example 2:** A system has an MTBF of 50 hours. What is the probability of two or more failures during a 10 hour mission?

**Solution:** Expected number of failures =  $\frac{t}{MTBF} = \frac{10}{50} = .2$ 

The probability of two or more failures is one minus the probability of one or less failures. From Table 5-6,  $P(r_1)$  when .2 are expected is .982.

Therefore, there is a very remote chance (1.8 percent) that a system with a 50 hour MTBF will experience two or more failures during a 10 hour mission.

**4.3 Poisson Example 3:** A system has an MTBF of 50 hours. What is the probability of experiencing two failures during a 10 hour mission?

**Solution:** Expected number of failures =  $\frac{t}{MTBF} = \frac{10}{50} = .2$ 

From Table 5-5, the probability of experiencing *exactly two* failures when .2 are expected is .017 or 1.7 percent. It should be noted that the probability of experiencing two or more failures, as determined in the last example, can also be determined from this table by adding P(r = 2) + P(r = 3) when .2 are expected.

## Appendix 6 Reliability Growth Testing

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-51

**1.0 RGT Definition:** MIL-STD-785 distinguishes reliability growth testing (RGT) from reliability qualification testing (RQT) as follows:

**Reliability Growth Test (RGT):** A series of tests conducted to disclose deficiencies and to verify that corrective actions will prevent recurrence in the operational inventory. (Also known as "TAAF" testing).

**Reliability Qualification Test (RQT):** A test conducted under specified conditions, by, or on behalf of, the government, using items representative of the approved production configuration, to determine compliance with specified reliability requirements as a basis for production approval. (Also known as a "Reliability Demonstration," or "Design Approval" test.)

**2.0 RGT Application Effectiveness:** An effective way to explain the concept of RGT is by addressing the most frequently asked questions relative to its use as summarized from "Reliability Growth Testing Effectiveness" (RADC-TR-84-20). For more information consult this reference and MIL-HDBK-189, "Reliability Growth Management."

Who pays for the RGT? Does the government end up paying more? The usual case is that the government pays for the RGT as an additional reliability program cost and in stretching out the schedule. The savings in support costs (recurring logistics costs) exceed the additional initial acquisition cost, resulting in a net savings in Life Cycle Cost (LCC). The amount of these savings is dependent on the quantity to be fielded, the maintenance concept, the sensitivity of LCC to reliability and the level of development required. It is the old "pay me now or pay me later situation" which in many cases makes a program manager's situation difficult because his or her performance is mainly based on the "now" performance of cost and schedule.

Does RGT allow contractors to "get away with" a sloppy initial design because they can fix it later at the government's expense? It has been shown that unforeseen problems account for 75% of the failures due to the complexity of today's equipment. Too low an initial reliability (resulting from an inadequate contractor design process) will necessitate an unrealistic growth rate in order to attain an acceptable level of reliability in the allocated amount of test time. The growth test should be considered as an organized search and correction system for reliability problems that allows problems to be fixed when it is least expensive. It is oriented towards the efficient determination of corrective action. Solutions are emphasized rather than excuses. It can give a nontechnical person an appreciation of reliability and a way to measure its status.

**Should all development programs have some sort of growth program?** The answer to this question is yes in that all programs should analyze and correct failures when they occur in prequalification testing. A distinction should be in the level of formality of the growth program. The less challenge there is to the state-of the-art, the less formal (or rigorous) a reliability growth program should be. An extreme example would be the case of procuring off-the-shelf equipment to be part of a military system. In this situation, which really isn't a development, design flexibility to correct reliability problems is mainly constrained to newly developed

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-53

interfaces between the "boxes" making up the system. A rigorous growth program would be inappropriate but a failure reporting and corrective action system (FRACAS) should still be implemented. The other extreme is a developmental program applying technology that challenges the state-of-the-art. In this situation a much greater amount of design flexibility to correct unforeseen problems exists. Because the technology is so new and challenging, it can be expected that a greater number of unforeseen problems will be surfaced by growth testing. All programs can benefit from testing to find reliability problems and correcting them prior to deployment, but the number of problems likely to be corrected and the cost effectiveness of fixing them is greater for designs which are more complex and challenging to the state-of-the-art.

# How does the applicability of reliability growth testing vary with the following points of a development program?

- (1) Complexity of equipment and challenge to state-of-the-art? The more complex or challenging the equipment design is, the more likely there will be unforeseen reliability problems which can be surfaced by a growth program. However, depending on the operational scenario, the number of equipments to be deployed and the maintenance concept, there may be a high LCC payoff in using a reliability growth program to fine tune a relatively simple design to maximize its reliability. This would apply in situations where the equipments have extremely high usage rates and LCC is highly sensitive to MTBF.
- (2) **Operational environment?** All other factors being equal, the more severe the environment, the higher the payoff from growth testing. This is because severe environments are more likely to inflict unforeseen stress associated with reliability problems that need to be corrected.
- (3) Quantity of equipment to be produced? The greater the quantities of equipment, the more impact on LCC by reliability improvement through a reliability growth effort.

What reliability growth model(s) should be used? The model to be used, as MIL-HDBK-189 says, is the simplest one that does the job. Certainly, the Duane is most common, probably with the AMSAA developed by Dr. Larry H. Crow of the Army Materiel Systems Analysis Activity second. They both have advantages; the Duane being simple with parameters having an easily recognizable physical interpretation, and the AMSAA having rigorous statistical procedures associated with it. MIL-HDBK-189 suggests the Duane for planning and the AMSAA for assessment and tracking. When an RQT is required, the RGT should be planned and tracked using the Duane model; otherwise, the AMSAA model is recommended for tracking because it allows for the calculation of confidence limits around the data.

**Should there be an accept/reject criteria?** The purpose of reliability growth testing is to uncover failures and take corrective actions to prevent their recurrence. Having an accept/reject criteria is a negative contractor incentive towards this purpose. Monitoring the contractor's progress and loosely defined

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-54

thresholds are needed but placing accept/reject criteria, or using a growth test as a demonstration, defeat the purpose of running them. A degree of progress monitoring is necessary even when the contractor knows that following the reliability growth test he will be held accountable by a final RQT. Tight thresholds make the test an RQT in disguise. Reliability growth can be incentivized but shouldn't be. To reward a contractor for meeting a certain threshold in a shorter time or by indicating "if the RGT results are good, the RQT will be waived," the contractor's incentive to "find and fix" is diminished. The growth test's primary purpose is to improve the design, not to evaluate the design.

What is the relationship between an RQT and RGT? The RQT is an "accounting task" used to measure the reliability of a fixed design configuration. It has the benefit of holding the contractor accountable some day down the road from his initial design process. As such, he is encouraged to seriously carry out the other design related reliability tasks. The RGT is an "engineering task" designed to improve the design reliability. It recognizes that the drawing board design of a complex system cannot be perfect from a reliability point of view and allocates the necessary time to fine tune the design by finding problems and designing them out. Monitoring, tracking and assessing the resulting data gives insight into the efficiency of the process and provides nonreliability persons with a tool for evaluating the development's reliability status and for reallocating resources when necessary. The forms of testing serve very different purposes and complement each other in development of systems and equipments. An RGT is not a substitute for an RQT or any other reliability design tasks.

How much validity/confidence should be placed on the numerical results of RGT? Associating a hard reliability estimate from a growth process, while mathematically practical, has the tone of an assessment process rather than an improvement process, especially if an RQT assessment will not follow the RGT. In an ideal situation, where contractors are not driven by profit motives, a reliability growth test could serve as an improvement and assessment vehicle. Since this is not the real world, the best that can be done if meaningful quantitative results are needed without an RQT, is to closely monitor the contractor RGT. Use of the AMSAA model provides the necessary statistical procedures for associating confidence levels with reliability results. In doing so, closer control over the operating conditions and failure determinations of the RGT must be exercised than if the test is for improvement purposes only. A better approach is to use a less closely controlled growth test as an improvement technique (or a structured extension of FRACAS, with greater emphasis on corrective action) to fine tune the design as insurance of an accept decision in an RQT. With this approach, monitoring an improvement trend is more appropriate than development of hard reliability estimates. Then use a closely controlled RQT to determine acceptance and predict operational results.

**3.0 Duane Model:** Because the Duane model is the one most commonly used, it will be further explained. The model assumes that the plot of MTBF versus time is a straight line when plotted on log-log paper. The main advantage of this model is that it is easy to use. The disadvantage of the model is it assumes that a fix is incorporated immediately after a failure occurs (before further test time is accumulated). Because fixes are not developed and implemented that easily in real

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-55

life, this is rarely the case. Despite this problem, it is still considered a useful planning tool. Below is a brief summary of the Duane model.

a. Growth Rate  

$$\alpha = \frac{\Delta MTBF}{\Delta TIME}$$
b. Cumulative MTBF  
MTBF<sub>c</sub> =  $\frac{1}{K} T^{\alpha}$   
c. Instantaneous MTBF  
MTBF<sub>1</sub> =  $\frac{MTBF_{c}}{1 - \alpha}$   
d. Test Time

$$T = \left[ (MTBF_1) (K) (1-\alpha) \right]^{\alpha}$$

e. Preconditioning period at which system will realize an initial MTBF of MTBFc

$$T_{pc} = \frac{1}{2} (MTBF_{PRED})$$

where

- k = a constant which is a function of the initial MTBF
- $\alpha$  = the growth rate

T = the test time

The instantaneous MTBF is the model's mathematical representation of the MTBF if all previous failure occurrences are corrected. Therefore, there is no need to selectively purge corrected failures from the data.

The scope of the up-front reliability program, severity of the use environment and system state-of-the-art can have a large effect on the initial MTBF and, therefore, the test time required. The aggressiveness of the test team and program office in ensuring that fixes are developed and implemented can have a substantial effect on the growth rate and, therefore, test time. Other important considerations for planning a growth test are provided in Table 6-1.

### Table 6-1: RGT Planning Considerations

- To account for down time, calendar time should be estimated to be roughly twice the number of test hours.
- A minimum test length of 5 times the predicted MTBF should always be used (if the Duane Model estimates less time). Literature commonly quotes typical test lengths of from 5 to 25 times the predicted MTBF
- For large MTBF systems (e.g., greater than 1000 hours), the preconditioning period equation does not hold; 250 hours is commonly used.
- The upper limit on the growth rate is .6 (growth rates above .5 are rare).

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-56

**4.0 Prediction of Reliability Growth Expected:** It is possible to estimate the increase in reliability that can be expected for an equipment undergoing a reliability growth development program. The methodology to do this is documented in RADC-TR-86-148 "Reliability Growth Prediction."

#### 4.1 Terms Explained:

- $\lambda_{\rm D}$  = MIL-HDBK-217 predicted equipment failure rate (failures per hour).
- $F_m$  = Equipment maturity factor. Estimated as the percentage of the design which is new.
- $K_1$  = Number of failures in the equipment prior to test.
- $K_1 = 30,000 \times F_m \times \lambda_p$
- $F_A$  = Test acceleration factor, based on the degree to which the test environment cycle represents the operational environmental cycle.

$$F_A = \frac{T_{OPERATIONAL}}{T_{TEST}} = \frac{\text{Length of operational life}}{\text{Length of test cycle}}$$

$$K_2 = \frac{0.0005}{6.5} (F_A)$$

#### 4.2 Prediction Procedure:

a. Calculate the equipment MTBF prior to test, MTBF(o):

MTBF(o) = 
$$\left[\lambda_{p} + \frac{0.0005K_{1}}{6.5}\right]^{-1}$$

b. Calculate the equipment MTBF after "t" hours of growth testing:

$$\mathsf{MTBF}(t) = \frac{\mathsf{F}_{\mathsf{A}}}{(\mathsf{F}_{\mathsf{A}})(\lambda_p) + \mathsf{K}_1\mathsf{K}_2\mathrm{e}^{-\mathsf{K}_2\mathsf{t}}}$$

c. Percent MTBF Improvement =  $\frac{\text{MTBF}(t)}{\text{MTBF}(o)} \times 100$ 

#### 4.3 Example:

To illustrate application of the reliability growth prediction procedure, consider the following hypothetical example of an avionics equipment to be subjected to reliability growth testing during full-scale development. The following assumptions are made:

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-57

- 40 percent of the equipment is new design; the remainder is comprised of mature, off-the-shelf items.
- The MIL-HDBK-217 MTBF prediction is 300 hours ( $\lambda_p = 1/300$ ).
- An RGT program is to be conducted during which 3000 hours will be accumulated on the equipment.
- The operational cycle for the equipment is a ten-hour aircraft mission.
- The test profile eliminates the period of operation in a relatively benign environment (e.g., the cruise portion of the mission) resulting in a test cycle of two hours.

The predicted number of failures in the equipment prior to testing is:

 $K_1 = 30,000 \times (0.4) \times (1/300) = 40$ 

The initial MTBF is:

MTBF(o) = 
$$\left[\frac{1}{300} + \frac{0.005(40)}{6.5}\right]^{-1}$$
 = 156 hours

The test acceleration factor is:

$$F_{A} = \frac{10}{2} = 5$$

The rate of surfacing failures during the test is:

$$K_2 = \left(\frac{0.0005}{6.5}\right) \times 5 = 0.0003846$$

The equipment MTBF after incorporation of corrective actions to eliminate those failures identified in the RGT program is:

MTBF(3000) = 
$$\frac{5}{(5 \times \frac{1}{300} + 40 \times 0.0003846 \text{ e}^{0.0003846 \times 3000})}$$
 = 232 hours

Hence, the predicted reliability growth is from an initial MTBF of 156 hours to an improved MTBF of 232 hours, approximately a 50 percent improvement.

#### ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-58

# Appendix 7 Maintainability/Testability Demonstration Testing

ROME LABORATORY RELIABILITY ENGINEER'S TOOLKIT

A-59

**1.0 Testing:** This appendix presents a listing of the possible maintainability demonstration plans as determined from MIL-STD-471 "Maintainability Verification Demonstration/Evaluation" and general plans for testability demonstrations. In most circumstances, maintainability and testability demonstrations are linked together and tested concurrently. Concurrent testing is cost effective and reduces the total number of tasks that must be demonstrated.

**2.0Maintainability:** For maintainability there are two general classes of demonstration: tests that use naturally occurring failures, and tests that require induced failures. Natural failure testing requires a long test period, while induced testing is only limited to the time to find fix the fault. To run a thirty task test using induced faults, the test time should be less than a week while a natural failure test could require six months or more depending on the failure frequency.

**2.1 Maintainability Test Recommendations** (See Table 7-1 for complete MIL-STD-471 Test Plan listing.)

- Test plan eight should be used if dual requirements of the mean and either 90th or 95th percentile of maintenance times are specified and a lognormal distribution is expected.
- Test plan nine should be used for mean corrective maintenance, mean preventive maintenance or combination of corrective and preventive maintenance testing. Any underlying distribution can be used in this test plan.
- The sample size of the tasks to be demonstrated should exceed 400 to reduce the risk of biasing the test results.
- The task samples must be based on the failure rate distribution of the equipment to be tested.
- Final selection of the tasks to be demonstrated must be performed by the procuring activity just prior to test.

**3.0 Testability:** Three parameters which are usually tested in a testability demonstration are: the fault detection capability, the fault isolation capability, and the false alarm rate. Fault detection and isolation parameters are demonstrated using induced faults, while false alarm demonstrations are based on naturally occurring events. (See Table 7-2 for more information on testability demonstration.)

#### 3.1 Testability Test Recommendations:

- Fault detection and isolation testing should be combined.
- Test samples should exceed 400 to reduce any bias.
- The test samples should be based on the failure rate distribution of the equipment to be tested.
- False alarm demonstration should be a data collection effort using all the contractor planned tests such as acceptance testing and initial operating tests (IOT).

#### 1.0 Air Force Databases

**G063: Maintenance and Operational Data Access System (MODAS):** MODAS is an on-line data storage and access system to track field maintenance events for purposes of product improvement, monitoring product performance and enhancing reliability and maintainability. The data base is menu driven and contains data on both ground and airborne equipment. Data can be sorted and accessed in several ways. For example, data on the top 50 most maintained subsystems on an aircraft can be viewed for a specific geographical area or for a specific aircraft platform. Mean-time-between-maintenance actions (MTBMA) can be calculated from the data on airborne systems because flight hours are also provided with the number of maintenance actions.

Air Force Materiel Command/ENIT Wright-Patterson AFB OH 45433-5001 (513) 257-6021 DSN: 787-6021

**Reliability and Maintainability Information System (REMIS):** REMIS is a central source on-line data access system containing all unclassified maintenance, operational, configuration and selected supply information for USAF weapon systems. REMIS, when completed, will be a conglomeration of almost all of the Air Force databases.

Air Force Materiel Command/MSC/SR Wright-Patterson AFB OH 45433-5001 (513) 429-5076 DSN: 787-5076

**D041: Requirements Computation System:** This system contains part failure rates and data assets for recoverable items.

Air Force Materiel Command/XRII Wright-Patterson AFB OH 45433-5001 (513) 257-5361 DSN: 787-5361

**Tactical Interim CAMMS and REMIS Reporting System (TICARRS):** This system reports on F-15 and F-16 aircraft inventory, utilization and maintenance.

Dynamics Research Corporation 60 Frontage Rd Andover MA 01810 (800) 522-4321, x2612

**G021: Product Quality Deficiency Reporting (PQDR):** This system provides procedures for assuring that the quality deficiency data generated by using activities are effective and appropriate management levels are apprised of quality problems. Also, it provides tracking to assure that corrective and preventive actions are carried out to alleviate future quality problems.

#### USAMC Materiel Readiness Support Activity Deficiency Reporting System

This system tracks equipment and component deficiencies for all equipments.

Commander USAMC Materiel Readiness Support Activity ATTN: AMXMD-RS Lexington KY 40511-5101 (606) 293-3577 DSN: 745-3577

#### 4.0 Other Government Databases

**Reliability Analysis Center (RAC):** RAC is a Department of Defense Information Analysis Center sponsored by the Defense Technical Information Center, managed by the Rome Laboratory, and currently operated by IIT Research Institute (IITRI). RAC is chartered to collect, analyze and disseminate reliability information pertaining to electronic systems and parts used therein. The present scope includes integrated circuits, hybrids, discrete semiconductors, microwave devices, opto-electronics and nonelectronic parts employed in military, space and commercial applications.

Data is collected on a continuous basis from a broad range of sources, including testing laboratories, device and equipment manufacturers, government laboratories and equipment users (government and non-government). Automatic distribution lists, voluntary data submittals and field failure reporting systems supplement an intensive data solicitation program.

Reliability data and analysis documents covering most of the device types mentioned above are available from the RAC. Also, RAC provides reliability consulting, training, technical and bibliographic inquiry services.

For further technical assistance and information on available RAC Services, contact:

Reliability Analysis Center 201 Mill Street Rome NY 13440-6916 Technical Inquiries: (315) 337-9933 Non-technical Inquiries: (315) 337-0900 DSN: 587-4151

**Government Industry Data Exchange Program (GIDEP):** The GIDEP program is a cooperative activity between government and industry participants for the purpose of compiling and exchanging technical data. It provides an on-line menu driven means of searching for desired information. Table 8-1 summarizes several separate GIDEP data banks which contain R&M related information.

Data Bank	Content
Engineering	Test reports, nonstandard part justification data, failure analysis data, manufacturing processes data.
Reliability and Maintainability	Failure mode and replacement rate data on parts, reports on theories, methods, techniques and procedures related to reliability and maintainability practices.
Failure Experience	Failure information generated on significant problems on parts, processes, materials, etc. Includes ALERTS and failure analysis information.

#### Table 8-1: GIDEP Data Bank Summary

GIDEP provides special services such as the ALERT system which notifies all participants of significant problem areas and the Urgent Data Request System which allows all participants queried for information to solve a specific problem. The current information found on-line is usually a brief summary of a report or collected data which provides a reference for further detailed information found on microfilm; however, GIDEP is working on a new system which will provide full text reports and ALERTS on-line.

#### 1.0 Specifications, Standards and Handbooks

This appendix provides a summary of military documents related to the R&M discipline. Table 10-1 lists reliability standards and handbooks along with an abbreviation to cross-reference the custodial agencies which are listed in Table 10-3. Table 10-2 lists maintainability standards and handbooks along with abbreviations of custodial agencies which are listed in Table 10-3. Table 10-4 lists other R&M related standards, specifications, pamphlets and regulations. Department of Defense Directives and Instructions may be obtained from the National Technical Information Service at the address shown at the bottom of this page. Copies of military specifications, standards and handbooks may be ordered from:

Standardization Document Order Desk 700 Robbins Ave. Building 4, Section D Philadelphia, PA 19111-5094 (215) 697-2667, -2179

#### 2.0 Rome Laboratory Technical Reports

Table 10-5 summarizes Rome Laboratory (formerly RADC) Technical Reports related to R&M design. Documents with a prefix of "A" in the AD number may be ordered by the general public from the National Technical Information Center. All others are available to DoD contractors from the Defense Technical Information Center.

	Analysis	EMP	Electronic Magnetic Pulse
DRAM	Dynamic Random Access	EO	Electro-optical
	Memory	EOS	Electrical Overstress
DRS	Deficiency Reporting	EP	Electrical Parameter
	System	EPROM	Erasable Programmable
DSP	Digital Signal Processing		Read Only Memory
DT&E	Development Test &	ER Part	Established Reliability Part
DTIC	Evaluation	ERC	Electrical Rule Check
DTIC	Defense Technical Information Center	ESC	Electronic System Center
DUT	Device Under Test	ESD	Electrostatic Discharge
DoD	Department of Defense	ESM	Electronics Support
DoD-ADL	Department of Defense		Measure
	Authorized Data List		
eV	Electron Volt		

A-99

ESS	Environmental Stress Screening	FPAP	Floating Point Array Processor
ETE	Electronic or External Test Equipment	FPLA	Field Programmable Logic Array
EW EXP	Electronic Warfare Exponent	FPMFH	Failure Per Million Flight Hours
FA	False Alarm	FPMH	Failures Per Million Hours
F/W	Firmware	FPPE	Floating Point Processing
FAB	Fabrication		Element
FAR	False Alarm Rate	FQR	Formal Qualification Review
FAR	Federal Acquisition	FQT	Final Qualification Test
	Regulation	FR	Failure Rate
FARR	Forward Area Alerting Radar Receiver	FRACAS	Failure Reporting and Corrective Action System
FAT	First Article Testing	FRB	Failure Review Board
FBT	Functional Board Test	FS	Full Scale
FCA	Functional Configuration	FSD	Full Scale Development
FD	Audit Fault Detection	FSED	Full Scale Engineering Development
FDI	Fault Detection and	FT	Fourier Transform
FET	Isolation Field Effect Transistor	FTTL	Fast Transistor - Transistor Logic
FFD	Fraction of Faults Detected	FY	Fiscal Year
FFI	Fraction of Faults Isolated	GAO	General Accounting Office
FFP	Firm Fixed Price	GD	Global Defect
FFRP	Field Failure Return Program	GFE	Government Furnished Equipment
FFT	Fast Fourier Transform	GFP	Government Furnished
FFTAU	Fast Fourier Transform Arithmetic Unit	GIDEP	Property Government Industry Data
FFTCU	Fast Fourier Transform Control Unit	GIMADS	Exchange Program Generic Integrated
FI	Fault Isolation		Maintenance Diagnostic
FIFO	First In First Out	GM	Global Memory
FILO	First In Last Out	GOCO	Government Owned Contractor Operated
FIR FITS	Fault Isolation Resolution Failure Per 10 <sup>9</sup> Hours	GOMAC	Government Microcircuit Applications Conference
FIT	Fault Isolation Test	GSE	Ground Support Equipment
FLIR	Forward Looking Infrared	GSPA	Generic Signal Processor
FLOTOX	Floating Gate Tunnel - Oxide	GaAs	Architecture Gallium Arsenide
FMC	Full Mission Capability	Hz	Hertz
FMEA	Failure Modes and Effects Analysis	HDL	Hardware Description Language
FMECA	Failure Modes, Effects and Criticality Analysis	HDS	Hierarchical Design System
FOM	Figure of Merit	HEMT	High Electron Mobility
FOV	Field of View		Transistor
FP	Floating Point		
FPA	Focal Plane Array
